REPORT ON THE QUALITY OF MARINE SURFACE OBSERVATIONS:

JANUARY TO JUNE 1994

CONTENTS

1. Introduction
2. Monitoring methods
3. Monitoring results:
 - 3.1 Pressure
 - 3.2 Wind
 - 3.3 Sea-surface temperature
4. Summary

REPORT ON THE QUALITY OF MARINE SURFACE OBSERVATIONS:

JANUARY TO JUNE 1994

LIST OF TABLES

1. Frequency distribution of the number of observations of pressure, wind and SST.
2. Number of observations of pressure for past six-month periods.
3. Platforms reporting suspect pressure observations:
 - 3a *Stations reporting in DRIFTR code.*
 - 3b *Stations reporting in SHIP code.*
4. Platforms reporting in SHIP code,not listed in table 3 but listed as suspect in the previous six-month period.
5. Platforms reporting suspect wind speed observations:
 - 5a *Stations reporting in DRIFTR code.*
 - 5b *Stations reporting in SHIP code.*
6. Platforms reporting in SHIP code,not listed in table 5 but listed as suspect in the previous six-month period.
7. Platforms reporting suspect wind direction observations:
 - 7a *Stations reporting in DRIFTR code.*
 - 7b *Stations reporting in SHIP code.*
8. Platforms reporting in SHIP code,not listed in table 7 but listed as suspect in the previous six-month period.
9. Platforms reporting suspect sea surface temperature:
 - 9a *Stations reporting in DRIFTR code.*
 - 9b *Stations reporting in SHIP code.*
10. Platforms reporting in SHIP code,not listed in table 9 but listed as suspect in the previous six-month period.

REPORT ON THE QUALITY OF MARINE SURFACE OBSERVATIONS:

JANUARY TO JUNE 1994

LIST OF FIGURES

1. Number of observations of pressure for past six-month periods.
- 2a Distribution of O-B SHIP pressure differences, all observations.
- 2b Distribution of O-B SHIP pressure differences, flagged observations only.
- 2c Distribution of O-B SHIP pressure differences, unflagged observations only.
- 2d-f As 2a-c but for wind speed.
- 2g-j As 2a-c but for wind direction.
3. Geographical distribution of bias of SHIP pressure.
4. Geographical distribution of standard deviation of SHIP pressure.
5. Geographical distribution of the number of SHIP pressure observations.
- 6-8 As figures 3-5 but for wind speed.
- 9-11 As figures 3-5 but for wind direction.
- 12a Number of observations of SST for each hemisphere & observation type.
- 12b Mean O-A of SST for each hemisphere & observation type.
- 12c Standard deviation of SST for each hemisphere & observation type.
- 13-15 As figures 3-5 but for SST.
16. As figure 5 but for fixed buoys and for SST.
17. As figure 5 but for drifting buoys and for SST.

REPORT ON THE QUALITY OF MARINE SURFACE OBSERVATIONS:

JANUARY TO JUNE 1994

1. INTRODUCTION

In 1985, the Commission for Basic Systems agreed that there was a need for GDPS/ Global NWP centres to monitor the quality of observations available on the GTS and to exchange monthly lists of those stations providing observations which seem in error. In 1988 three lead centres were nominated which would have a co-ordinating role of producing, at six-monthly intervals, consolidated lists of suspect stations for given data types together with information on the nature of the error. RSMC Bracknell was allocated the role as lead centre for marine surface observations which encompasses observations from ships, drifting buoys, moored buoys and other fixed marine platforms. This is the eleventh such report and covers the period January to June 1994. The report covering the period July to December 1994 will appear in spring 1995.

Following the CBS recommendations, four centres have been active in exchanging monitoring information each month; RSMC Bracknell since August 1987, ECMWF since August 1988, RSMC Tokyo since September 1988 and NMC Washington since August 1989. At first, the only monitoring information exchanged on marine surface observations was related to pressure, and the first two WMO reports were restricted to that parameter alone. All four centres now regularly monitor wind observations and results are contained in this report. In addition, the report contains monitoring results for sea-surface temperature (SST). For each marine observing platform identified as suspect, values are supplied for the number of observations received at each centre, the number of observations with gross errors, and the mean and rms differences from the background values used by the numerical data assimilation system.

2. MONITORING METHODS

Errors in observations may arise from a number of sources: the instrument may be malfunctioning, figures may be mistaken while being transferred manually, or there may be corruption of data during transmission. Errors can also arise in the pressure report if the adjustment to sea level is made incorrectly or not at all, and a poorly-sighted anemometer can result in errors in the observations of wind. For SST observations, the depth at which the observation is made can be crucial. "Surface" observations from buoys are usually made at a depth of around 0.5m, whereas ships may take a measurement between a depth of 10m and the surface, depending on the method used. At present, there is no indication given within the report of the observation's depth, so it is not possible to determine the significance of this factor. By contrast, satellites measure the temperature of the ocean's "skin" which is generally slightly cooler than the temperature immediately beneath, by several tenths of a °C, as a result of evaporative cooling and other surface processes. Some of these errors can be detected by applying checks on the code format and the internal consistency of the report (for example: are the position and pressure consistent with a report 6 hours earlier?). Checks on spatial consistency may be made if there are other nearby observations. However, such quality checks are unable to identify errors on all occasions and it is recognised that the numerical data assimilation systems in use today can provide global reference values which have a valuable application in the area of observation monitoring. The background field, or the short-term forecast from the previous numerical analysis, provides perhaps the most useful information on observation quality, as it represents an accurate and spatially consistent estimate of the observed value which is independent of the observation itself. Observation-minus-background (hereafter referred to as O-B) differences are at the centre of all monitoring work by GDPS centres. For sea-surface temperature, it is not possible to use a

background field with which to compare the observed value, as for wind and pressure observations, because no forecast of SST is performed. Instead, the analysis field is used. SST changes only slowly relative to parameters above the surface, thus this is a good enough approximation. Analyses are performed daily at RSMC Bracknell from an assimilation of both surface and satellite observations. There is one drawback in using the analysis field as an alternative: it is not independent of the observations themselves. This is a major limitation when it comes to assessing observation quality since the results are not straightforward to interpret.

Taking all marine surface observations together, the values of O-B have distinct characteristics. The vast majority of the observations show quite small departures from background and the distribution of O-B is nearly Gaussian, with little or no bias. The errors in the background field probably contribute most to the values of O-B for these observations. There is, however, often a smaller group of observations departing much more from background, for which observation error is the only reasonable explanation for the large values of O-B. Studies of the distribution of O-B and its variation at different points around the globe enable reasonably accurate estimates of background error to be made, and this provides the basis for the monitoring methods described here. Those marine observing platforms for which, in a sufficiently large sample, the observed values of pressure or wind differ from the background by an amount significantly in excess of the estimate of background error, may be labelled as suspect with a high degree of confidence. The limits used here to identify suspect observing platforms have been set sufficiently stringent to preclude much likelihood of the background, rather than the observations, being in error.

Each monitoring centre produces a monthly list of the identifiers of marine observing platforms considered suspect according to the departure from the centre's background values. All observations, both synoptic and asynoptic, are assimilated. At Bracknell, Tokyo and Washington, the corresponding background value used is that valid at the nearest main synoptic hour. At ECMWF, however, interpolation in time is performed.

Given that the number of observations made during the month is greater than or equal to 20, then the condition used by all centres for obtaining platforms for the suspect lists is that at least one of the following criteria are satisfied:

Pressure

1. the $| \text{mean of O-B} | \geq 4.0 \text{ hPa}$
2. the standard deviation of O-B $\geq 6.0 \text{ hPa}$
3. the percentage of gross errors ≥ 25

Wind

1. the $| \text{mean of O-B} | \geq 5.0 \text{ ms}^{-1}$ (Speed)
 $\geq 30^\circ$ (Direction)
2. the standard deviation of O-B $\geq 80^\circ$ (Direction)
3. the percentage of gross errors ≥ 25

A gross error is defined as an observation which departs from the background by more than 15hPa (Pressure) or 25ms^{-1} (Vector Wind). The mean and standard deviation of the samples are evaluated excluding gross errors and in this way occasional "wild" values resulting from, for example, corruption during transmission, do not influence the sample characteristics. Direction statistics are also calculated excluding values in light winds, where either the observed or background speed is less than 5ms^{-1} .

Very little information is exchanged between centres on a regular monthly basis for SST.

The monthly results for pressure from all four monitoring centres show considerable agreement, both on the observing platforms listed as suspect and the values of the mean and rms difference from each centre's background. Differences between the monthly suspect lists are usually due to

the different numbers of observations available at each centre. The cut-off varies between 6 and 24 hours. There are also some unexplained variations in the data receipt between the centres, which may be due to problems in the GTS or in the local procedures for handling the data. Monitoring information for wind speed is regularly exchanged between ECMWF, NMC Washington, RSMC Tokyo and RSMC Bracknell, with reasonable agreement on the mean and standard deviation from each centre's background; there is less agreement as to which platforms are listed, reflecting the greater uncertainty when monitoring wind speed.

This report draws together all the monthly monitoring results exchanged on marine surface data and identifies a list of observing platforms which have provided observations of poor quality over the six-month period. In drawing-up this list, there have been a number of guiding principles:

1. As with the monthly lists, accuracy is assessed relative to background values.
2. Only those observing platforms are listed for which there is a very high degree of confidence that the observations rather than the background values are in error.
3. At least 40 reports are required over the period in which the observations are considered suspect.
4. The perceived accuracy over the last part of the six-month period is of greatest importance; observing platforms will not be listed if there has been recent improvement and their reports are at present without major error.
5. Given that the number of observations made during the period is greater than or equal to 40, then the condition for listing a platform as suspect in this report is that at least one of the following criteria are satisfied:

Pressure

1. the | mean of O-B | \geq 3.5 hPa
2. the standard deviation of O-B \geq 5.0 hPa
3. the percentage of gross errors \geq 25

Wind

1. the | mean of O-B | \geq 5.0 ms⁻¹ (Speed)
 \geq 30° (Direction)
2. the standard deviation of O-B \geq 6.0 ms⁻¹ (Speed)
 \geq 60° (Direction)
3. the percentage of gross errors \geq 25

SST

1. the RMS of O-A \geq 2.5 °C
2. the percentage of gross errors \geq 25

The same gross error limits apply in this report as for the monthly lists, with the limit for SST being set at 5°C. All observations having gross errors are excluded from the calculation of the mean and standard deviation of O-B and O-A.

The limits set on the bias and standard deviation of O-B are slightly less stringent than those for the monthly lists because the sample sizes are larger. They are only applied over the last part of the period if there has been a recent deterioration in quality. It is possible that there are a few observing platforms listed in this report which have not appeared on any of the monthly lists. This can occur if they report infrequently and only produce a large enough sample over a period of several months. The six-month list is longer than most of the monthly lists because many ships cease reporting for variable periods of time, presumably in most cases while they are in port or

out of service. Only over a relatively long period, probably more than six months, is a representative sample obtained from all those ships providing observations.

3. MONITORING RESULTS

The monitoring results presented in this report only relate to data exchanged over the GTS. Observations from marine platforms are transmitted in one of two formats: the SHIP code, used for most observations from ships, moored buoys and other fixed platforms, and the DRIFTR code, used mostly for observations from drifting buoys. In this report the term "ship observations" refers to those received in the SHIP code and the "drifting buoy observations" to those received in DRIFTR code. The SHIP code indicates whether the observation was made manually or by an automatic system and accordingly the sub-divisions "manual ship" and "automatic ship" will be defined.

3.1 Pressure

In the six-month period January to June 1994, 726025 observations of pressure were monitored at Bracknell from 6008 manual ships, 289 drifting buoys, and 362 automatic ships. The number of reports received from individual ships varies greatly as Table 1 demonstrates. Apparently, a very large percentage only report once. The reason for this is unclear but it may be a result of errors in the part of the message giving the ship identifier. A comparison with the corresponding table in the tenth report, shows that the number of identifiers has decreased across the complete range of platform types and variables; this is particularly noticeable for drifting buoys observing wind.

TABLE 1: FREQUENCY DISTRIBUTION OF THE NUMBER OF REPORTS OF PRESSURE, WIND AND SEA SURFACE TEMPERATURE FROM INDIVIDUAL IDENTIFIERS AVAILABLE FOR MONITORING AT BRACKNELL, JANUARY TO JUNE 1994.

Number of reports	Number of manual ships reporting			Number of drifting buoys reporting			Number of automatic ships reporting		
	Press	Wind	SST	Press	Wind	SST	Press	Wind	SST*
1	1966	1704	2102	19	15	0	89	81	4
2-10	1003	982	1026	20	13	18	51	54	115
11-20	422	420	373	11	5	14	16	22	14

* numbers are for automatic (fixed) buoys only

Table 2 shows the number of observations of pressure that have been received over the GTS at Bracknell for past six-month periods. Due to changes in data storage methods at Bracknell in May 1991, report number 5 covered the period January to May 1991 only, thence figures for January-June 1991 have been scaled-up in order to make a fair comparison with other six-month periods; this may not be entirely accurate. Further changes in November 1993 for drifting buoys & automatic ships for pressure & winds, may have allowed duplication of a few identifiers in Table 1 for the period June to December 1993, as reclassification from one observation type to another

occurred. The observation distribution shown in Table 2 will also have been affected in the long term with a slight shift towards drifting buoys; no duplication of observations occurred however. SST observations were not affected by the November 1993 change.

NUMBER OF OBSERVATIONS OF PRESSURE RECEIVED AT BRACKNELL ON THE GTS FOR EACH OF THE SIX-MONTH PERIODS COVERED BY THE WMO REPORTS ON THE QUALITY OF MARINE OBSERVATIONS

TABLE 2:

Period	WMO report number	Number of Observations			
		Manual ships	Drifting buoys	Automatic ships	Total
Jan-Jun 1989	1	424087	174971	40082	639140
Jul-Dec 1989	2	421315	151972	58016	631303
Jan-Jun 1990	3	424335	177927	63847	666109
Jul-Dec 1990	4	412430	205488	71146	689064
Jan-Jun 1991	5	364760	177069	64401	606230
Jul-Dec 1991	6	348710	148604	68456	565770
Jan-Jun 1992	7	332443	216872	73893	623208
Jul-Dec 1992	8	336958	247873	80862	665693
Jan-Jun 1993	9	340293	288208	77317	705818
Jul-Dec 1993	10	348082	316261	88650	752993
Jan-Jun 1994	11	334134	279963	111928	726025

FIGURE 1:

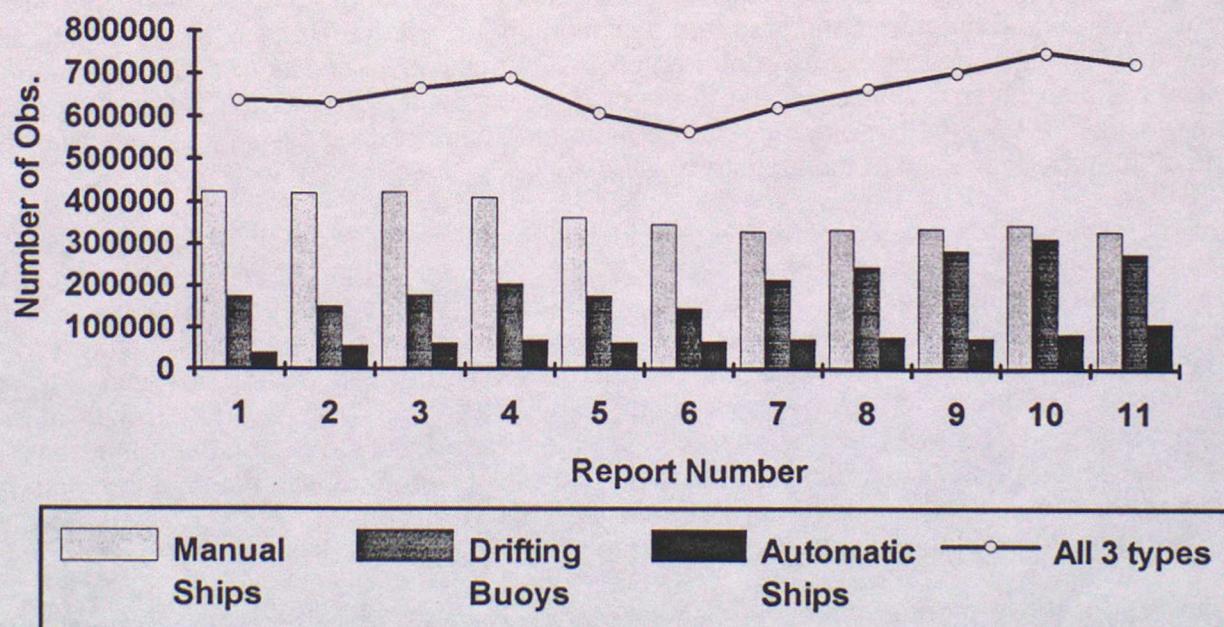

Figure 1 shows the information presented in Table 2 more clearly. It can be seen that the total number of observations rose somewhat to begin with, but was followed by a notable decline. Since report number six (covering the period July to December 1991) however, there has been a recovery in the total, with the latter half of 1993 showing the greatest number of all. At first the

increase was mainly due to an increase in the number of drifting buoys reporting; more recently however, the number of buoys has stabilised to some extent, but the increase in the number of reports from each buoy continues, as reliability improves. In this latest six month period, the total number of reports from both ships and drifting buoys has once again declined, with the shift towards automatic ships appearing to have accelerated. Overall however, the number of observations has decreased slightly.

A histogram of O-B differences for all ship pressure reports in the period January to June 1994 is shown in Figure 2a, together with the Gaussian distribution with the same mean and standard deviation. Although almost all values fall within the range +5 to -5 hPa, a small number of very large values, presumably resulting from erroneous observations, contribute to the large standard deviation of the population. The distribution for all those observations which fail the automatic quality-control checks is broad and bimodal (Figure 2b). The remaining 95 per cent of the observations which pass the quality checks show a distribution of O-B which is very close to Gaussian (Figure 2c) with mean -0.1 hPa and standard deviation 1.4 hPa; the principal contribution to the standard deviation is assumed to be from background errors.

A global estimate of the background error, such as is provided above, will conceal large variations which may occur from place to place. Background values will be more accurate in data-rich areas (eg: in the North Sea or Mediterranean) or where the meteorological variability is low (eg: the tropics). The geographical distributions of the mean and standard deviation of the values of O-B from all ship observations which pass the quality-control checks, have been calculated for 10-degree latitude-longitude boxes and are plotted in Figures 3 and 4. In almost all areas the magnitude of the mean is less than 1.0 hPa, the exceptions being generally only where the sample size is small; in fact, with these exceptions plus the Pacific Ocean, many areas show a magnitude of less than 0.5hPa. The standard deviation in the tropics is 1.0 to 1.5 hPa, in northern latitudes 1.5 to 2.0 hPa, and in the Southern Ocean 2.0 to 3.0 hPa. The number of ship pressure reports accepted by the model quality control in each 10-degree box is shown in Figure 5.

Table 3 contains a list of those ships and drifting buoys considered to have produced suspect observations of pressure in the period January to June 1994. Values over the six-month period are given for the number of observations of pressure available for the Bracknell global model runs, the number of observations differing from the background value by more than 15 hPa (gross errors), and the mean and standard deviation of O-B using the Bracknell global model. The number of times the identifier has appeared on the monthly suspect lists from the four monitoring centres is also given. In order to give a detailed picture of the frequency of reporting and any changes in the observation accuracy, six-month time-series of O-B differences are given at the end of the report for each of the identifiers listed.

An interesting characteristic of the errors identified here, which soon becomes obvious on inspection of the time-series charts at the end of this report, is that most can be attributed to a bias in the observed pressure. In many cases the bias is constant over the whole monitoring period. There are some values which appear to depart greatly from the sample mean, presumably due to some gross error in the observation, but generally they are isolated instances. In only a few cases are there regular large random departures from background. Those observing platforms listed in Table 3 which appeared in the tenth report (July to December 1993) have been indicated with an asterisk. A comparison of the statistics given here with those in the ninth report (January to June 1993), clearly indicates that the bias in the pressure observations from some ships has scarcely changed over the past 12 months.

Statistics for those marine observing platforms which were listed in the tenth six-monthly report and which do not appear in Table 3b, are given in Table 4 along with comments on the quality of their pressure observations. Time-series charts of the pressure observations from these platforms are not given. Less than 40 reports have been received in the latest six-month period for a majority of the ships on this list; several show some improvement in the quality of observations, however.

3.2 Wind

The monitoring of observations of wind, presents more problems than for pressure. On the majority of observing platforms, wind is measured using anemometers. The reported speed will be dependent on the averaging period and the height of the instrument above sea level, which will vary a great deal from platform to platform. The wind flow is distorted by a large structure and factors affecting the wind measurement will also include the siting of the anemometer and the bearing of the wind with respect to the structure. Not all winds are measured by anemometers; observations from some ships are based on visual estimates of the sea state and in these cases the factors outlined above do not apply.

In the monitoring results presented here, the background winds are valid at a height of 10 metres above mean sea-level, a little lower than the average height of a ship anemometer. Where the anemometer height is much different from the reference height a significant O-B speed bias may be introduced. This will be the case, for example, for observations from oil rigs or tankers with an anemometer height of 50m or more, or from buoys where the anemometer can be as low as 2m.

In the period January to June 1994, 414173 observations of wind were available for monitoring at Bracknell from 5509 manual ships, 49 drifting buoys, and 413 automatic ships. A more detailed breakdown is given in Table 1. Histograms of O-B differences for ship observations of wind speed are presented in Figures 2d to 2f and of wind direction in Figures 2g to 2j. As with observations of pressure, those wind observations which fail the quality-control checks differ most from background, some by as much as 50ms^{-1} , and they make a large contribution to the variance of O-B. The distributions of O-B wind speed and direction for the remaining 91 per cent of the observations are nearly Gaussian. There is a speed bias of $+1.4\text{ms}^{-1}$ relative to background, with a direction bias of just -1.7° .

Figures 6 and 7 show the geographical distributions over the six-month period of the mean and standard deviation of O-B for ship observations of wind speed which pass the quality-control checks. The numbers of wind reports used to generate these statistics are presented in Figure 8. The standard deviation of O-B wind speed is typically 3 to 4ms^{-1} in middle latitudes and less than 3ms^{-1} in the tropics. The bias is generally around $+1\text{ms}^{-1}$, but exceeds $+2\text{ms}^{-1}$ in a few places. Similar distributions of the mean and standard deviation of O-B wind direction are shown in Figures 9 and 10. Only reports where both the observed and background wind speeds are greater than 5ms^{-1} were used to obtain these values. The magnitude of the bias is less than 10 degrees in most places. The standard deviation is generally between 20 and 30 degrees globally, but in some areas, notably tropical parts of the Indian and Pacific Oceans & in data-sparse areas of the southern hemisphere, it is as large as 40 or 50 degrees. The numbers of reports of wind direction used to generate these statistics are presented in Figure 11.

Figures 6-11 provide reference values against which the characteristics of O-B for different marine observing platforms may be compared. Table 5 contains a list of those ships and drifting buoys considered to have produced suspect observations of wind speed in the period January to June 1994, and in Table 7 a similar list is provided for wind direction. Values are given for the number of observations of wind received at Bracknell, the number of observations having a vector difference from background of more than 25ms^{-1} (gross errors), & the mean and standard deviation of O-B. Time-series of O-B for each identifier listed are given at the end of the report. In most cases of suspect speed observations, a constant bias is clearly evident. Errors in observations of direction are more random in nature. Tables 6 & 8 contain statistics for platforms which are not included in Tables 5 & 7 but that were listed in the previous six-month report, for wind speed & direction respectively. Time-series plots for these identifiers are not included in this report.

3.3 Sea-surface temperature

In the six-month period, January to June 1994, a total of 1054413 observations of SST were monitored at RSMC Bracknell. Of these, 321765 were from ships, 267355 from fixed buoys and 465293 from drifting buoys. This is a decrease of 25756 compared with the six-month period July

to December 1993. The decrease is due to a decrease in the number of observations from both ships and fixed buoys, but is offset by a slight rise in reports from drifting buoys. The number of ships reporting SST has decreased by around 10% compared with the previous six months, with the number of drifting buoys reporting decreasing by more than 15%; the number of fixed buoys reporting has also decreased slightly. Table 1 gives the number of reports received from individual identifiers in frequency categories and shows that a large number of ships and fixed buoys reported only once during the six-month period. Errors in reporting the station's identifier could make a significant contribution to these totals. Despite there being a relatively small number of buoys, they constitute a substantial percentage of the total number of observations received. This is due to the frequency at which the observations are made: ships usually report only at the main synoptic hours, or less frequently, whereas some buoys report as often as every hour.

Figures 12a, 12b and 12c show the number of observations, mean O-A and standard deviation of O-A for each of the 3 observation types, for both the northern and the southern hemispheres. Only observations passing quality control checks have been used. Figure 12b shows that the overall bias of each observation type is small ($< 0.1^{\circ}\text{C}$), with ship observations having a slightly positive bias and fixed and drifting buoys a slightly negative bias. Figure 12c shows that ship observations are substantially more erratic, with standard deviations approximately twice those of fixed and drifting buoys. This is partly due to the fact that buoys report frequently and at a quasi-constant location which effectively gives them increased weight in the analysed field.

Figures 13, 14 and 15 respectively show the global distribution of the bias and standard deviation of O-A and the numbers of observations, for ships. The largest biases occur at high latitudes, which is most likely a result of the small number of observations available and hence the decreased reliability of the analysis in these areas, particularly in the southern hemisphere. Figures 16 and 17 show the global distribution of fixed and drifting buoy SST reports. The coverage provided by drifting buoys is extensive, with particularly good coverage over the bulk of the Pacific Ocean. Only a limited number of platforms report in the Indian Ocean and tropical parts of the Atlantic Ocean. Fixed buoys are largely concentrated in coastal regions, with particularly high observation densities around the UK and the USA. A number of $10^{\circ} \times 10^{\circ}$ grid boxes contain less than 5 reports; this situation may have arisen from reports containing erroneous positions.

Table 9 contains a list of the ships and drifting buoys considered to have produced suspect observations over the six-month period. The comments given in each case provide an indication of the main reason for the station to be listed as suspect. Table 10 gives details of the performance over the latest six-month period of ships which were considered suspect in the previous six-month period but which don't appear in Table 9. A significant number of the ships included in Table 10 have shown an improvement in the accuracy of SST measurements during the first six months of 1994. No time-series charts have been plotted for SST so the comments are based on a comparison of the magnitudes of the mean, root-mean-square error and standard deviation of O-A. A large number of the identifiers appearing on the list do so as a result of a persistent bias. A high percentage of those listed due to the number of gross errors, also show a large bias.

4. SUMMARY

72 marine observing platforms are listed as producing suspect observations of pressure over the period January to June 1994, 27 as producing suspect wind observations and 130 as producing suspect SST observations. The first report issued by RSMC Bracknell for the period January to June 1989, listed 150 marine platforms producing suspect observations of pressure. The selection criteria have remained unchanged, and the reduction in the number of platforms listed seems to reflect a genuine improvement in quality over the period.

The most common characteristic of the pressure errors found here is a bias in the reported pressure which may remain constant for many months. The majority of platforms listed as producing suspect wind observations show a bias in the reported wind speed, while a few show a large standard deviation in wind direction. For sea-surface temperature observations, the presence of a persistent bias is again found to be the most common cause of error.

The selection criteria have been set sufficiently stringent to ensure that only those are listed for which there is a high degree of confidence in there being large observation errors. There are a great many others, not listed here, for which there must be considerable doubt over the quality of the observations. A wider range of monitoring results are available from Bracknell on request.

TABLE 3: LIST OF MARINE OBSERVING PLATFORMS REPORTING SUSPECT PRESSURE OBSERVATIONS OVER THE PERIOD JANUARY TO JUNE 1994.

- Column 1 Call sign or identifier.
 Column 2 Number of pressure observations available for monitoring over the 6-month period, excluding duplicates, but including any observations with gross errors.
 Column 3 Number of pressure observations differing by more than 15 hPa from background (gross error).
 Column 4 Standard deviation of observation-minus-background differences excluding cases of gross error.
 Column 5 Mean of observation-minus-background differences (bias) excluding cases of gross error.
 Columns 6-9 Number of times observing platform has appeared on suspect lists.
 B=Bracknell, E=ECMWF, T=Tokyo, W=Washington.
 Column 10 Comments on quality of pressure observations.

- Notes:**
1. Units are hPa.
 2. Observing platforms marked with an asterisk were listed in the previous report (July to December 1993)

ii): *Platforms operational at the end of the reporting period*

There are no platforms that fall into this category

Note:

All identifiers appearing to be suspect have been included in the above tables. However, inspection of the corresponding time-series reveals that some of the buoys report only for a very brief period. It may be possible that these buoys never actually observed wind, but that occasionally reports were coded as calm instead of missing.

**TABLE 10: LIST OF PLATFORMS REPORTING IN SHIP CODE NOT APPEARING IN TABLE 9
BUT LISTED AS SUSPECT OVER THE PERIOD JULY TO DECEMBER 1993.**

- Column 1 Call sign or identifier
 Column 2 Number of sea-surface temperature observations available for monitoring over the 6-month period, including any observations with gross errors.
 Column 3 Number of sea surface temperature observations differing by more than 5°C from the analysis (gross errors).
 Column 4 Standard deviation of observation-minus-analysis differences excluding cases of gross error.
 Column 5 Mean of observation-minus-analysis differences excluding cases of gross error.
 Column 6 Comments on quality of sea surface temperature observations.

Notes: 1. Units are °C.

VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 58

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: ELG12
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 45

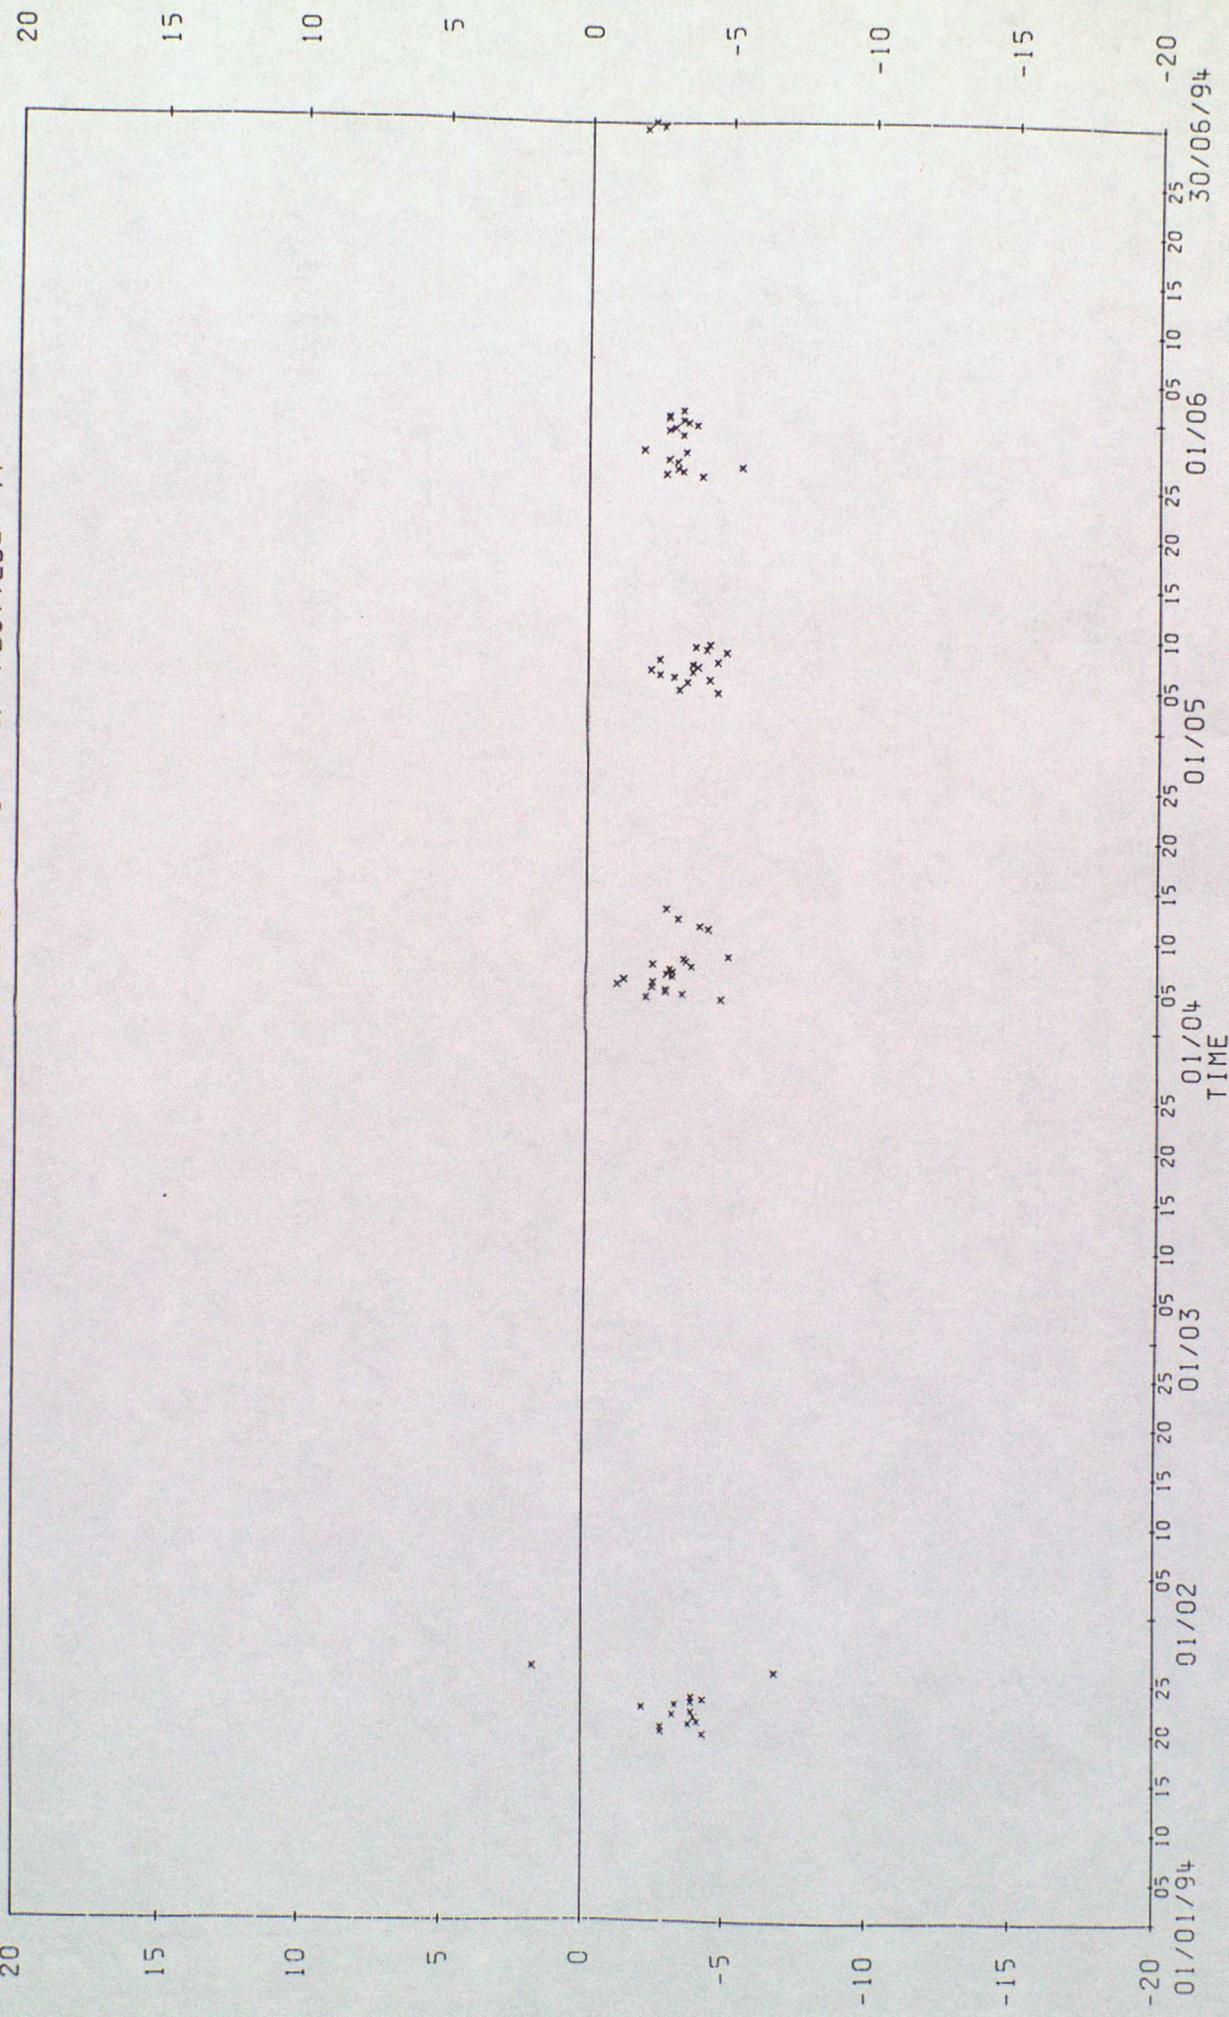

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: ELIU4
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 1 N. PLOTTED= 157

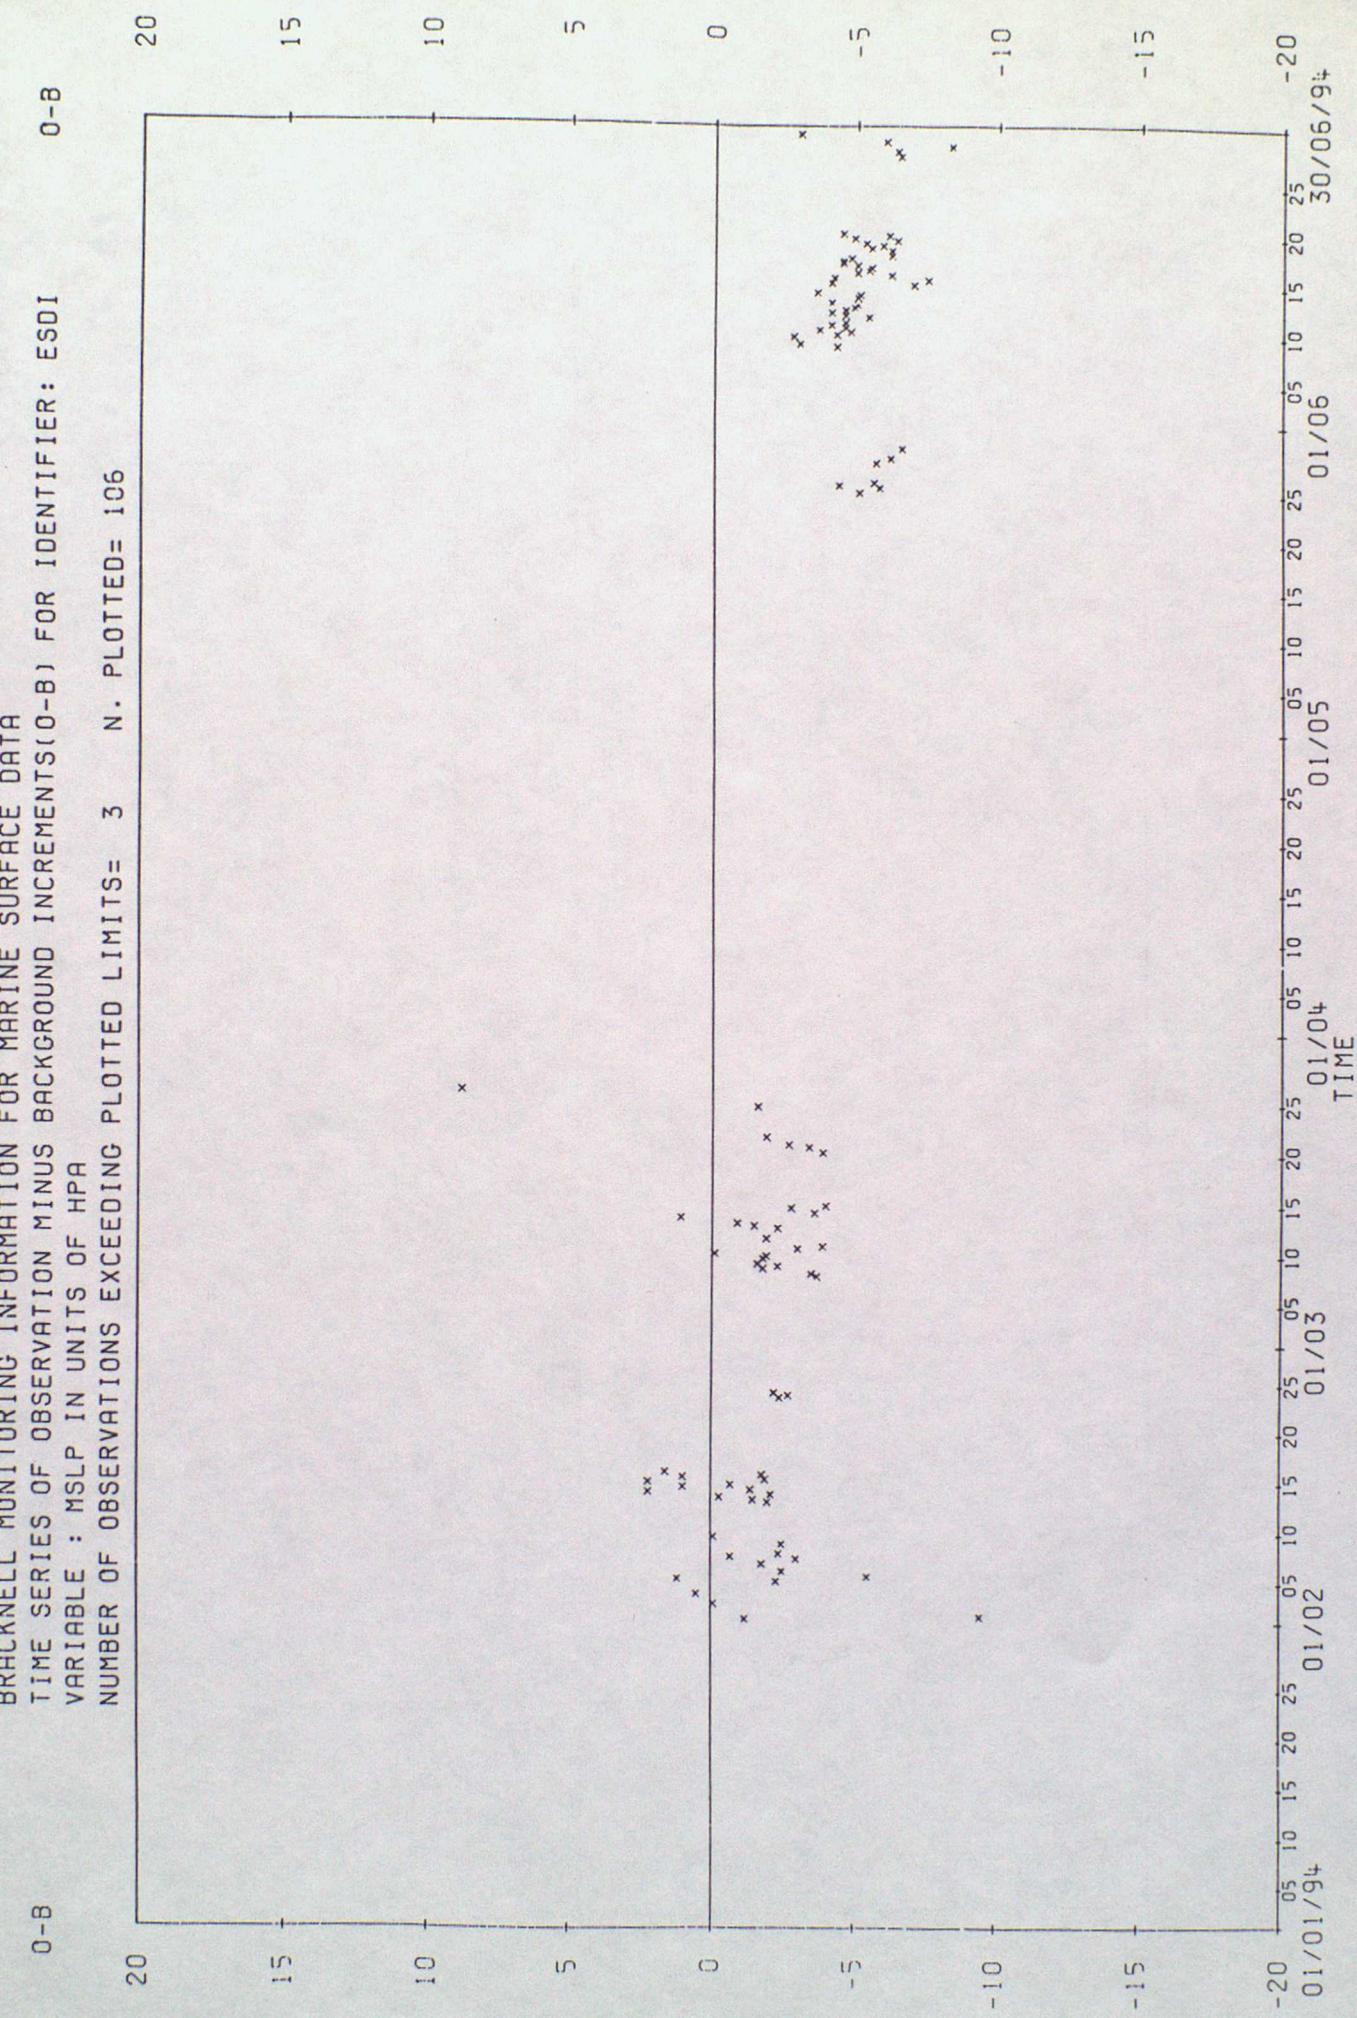

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: ELND2
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 122

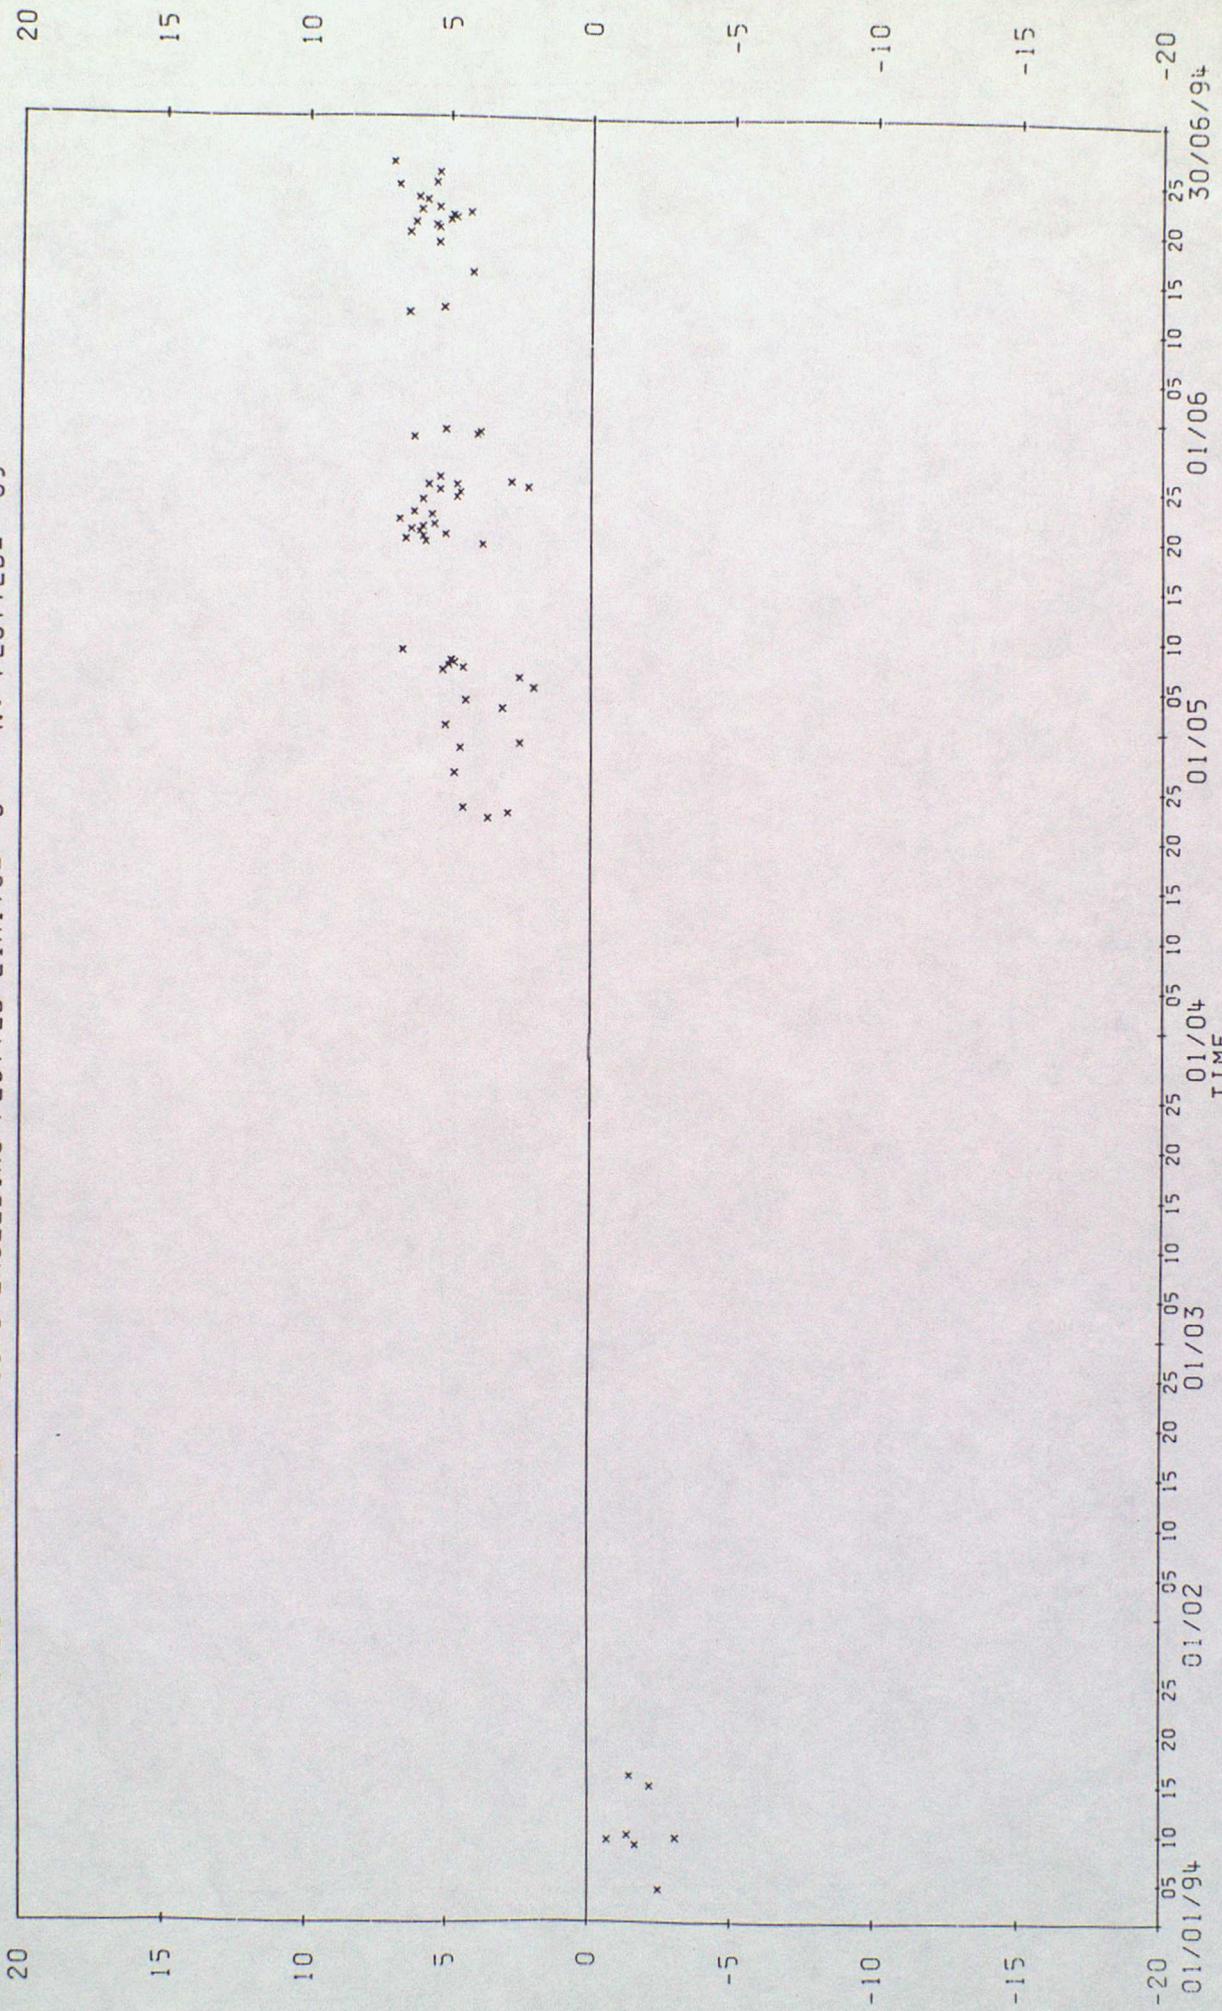

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: ELPZ3
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 74

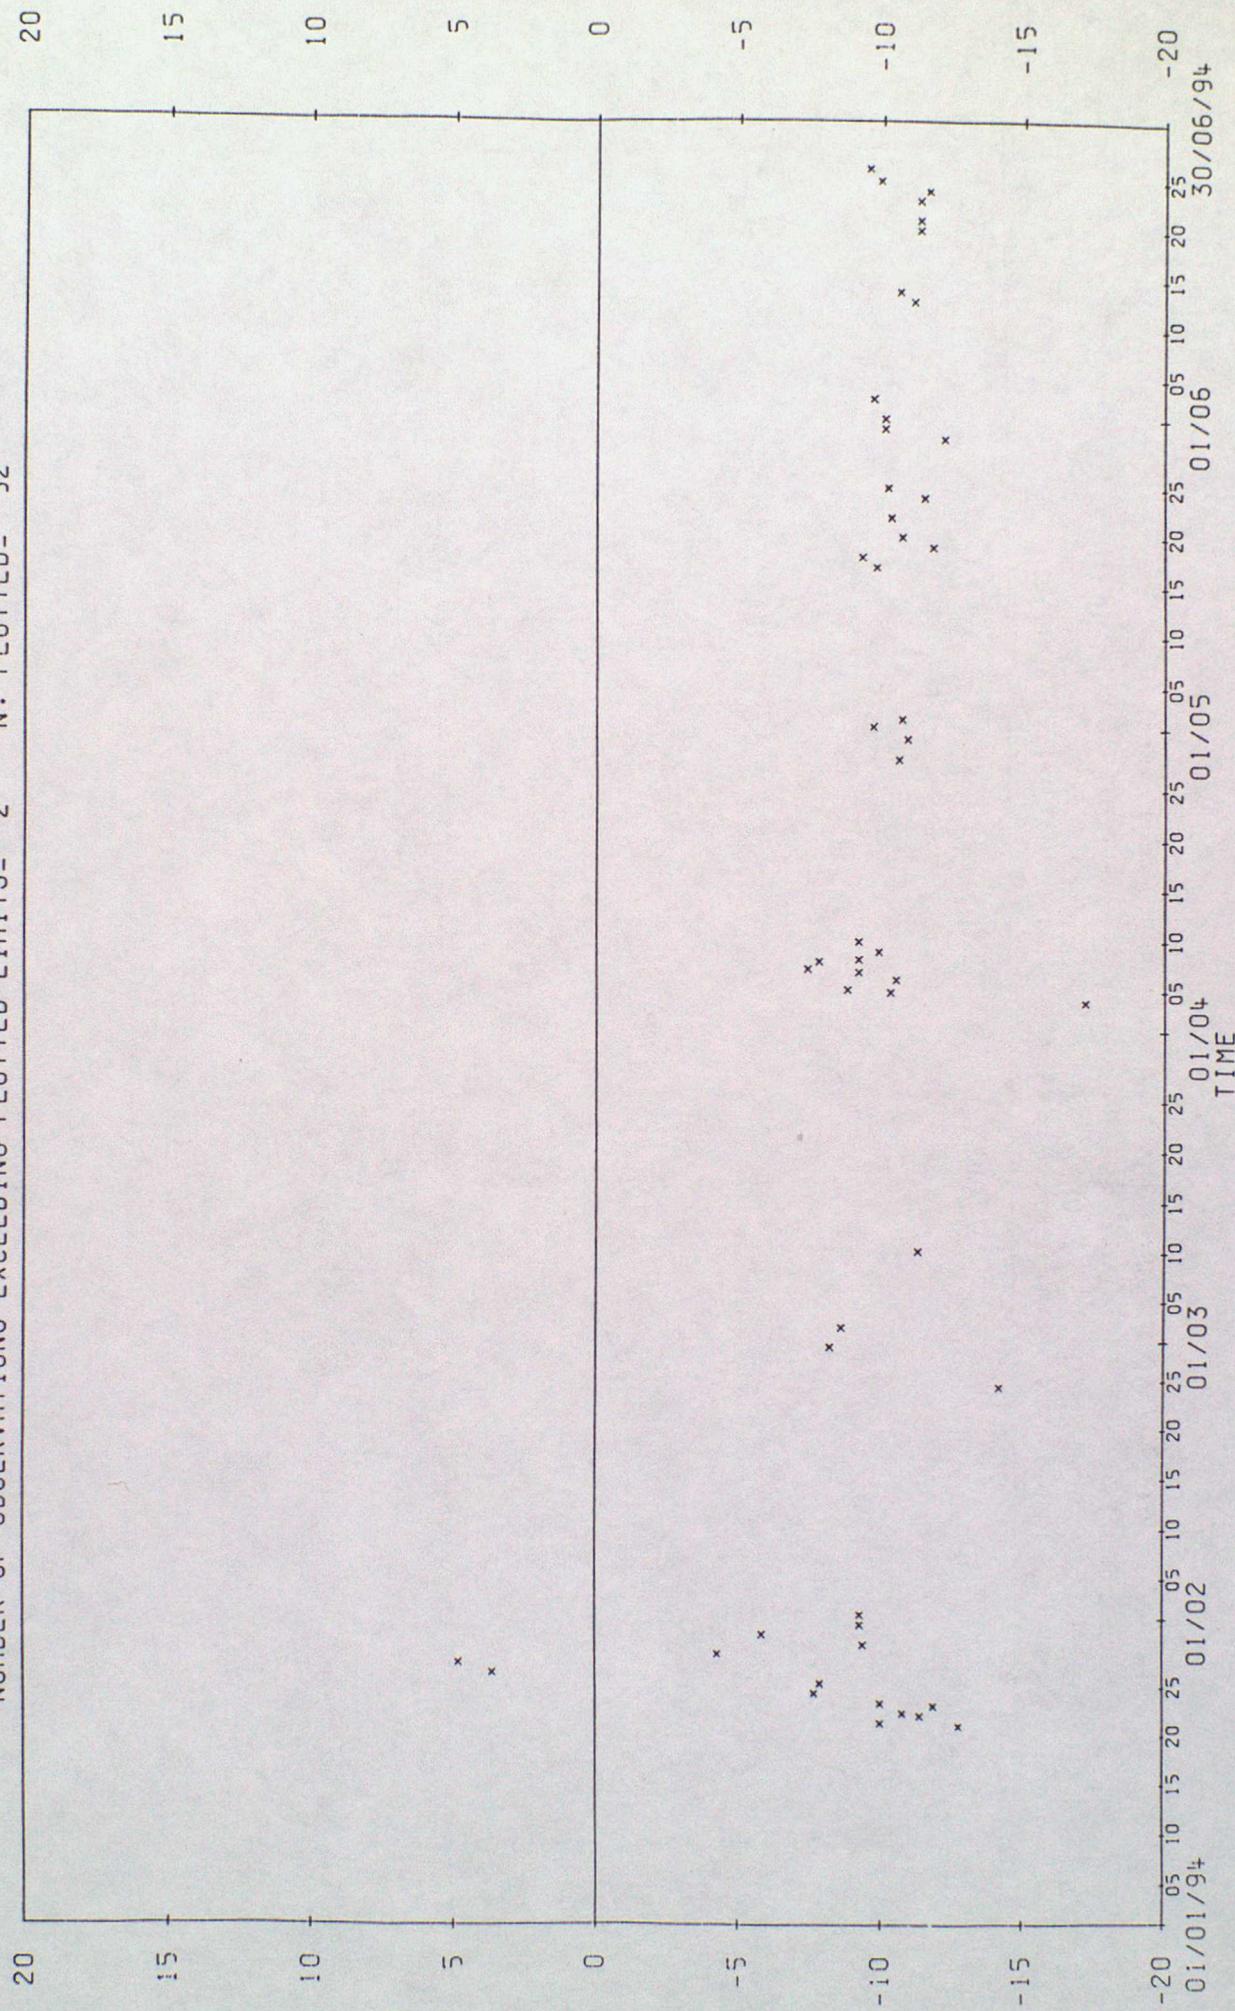

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: ESDI
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 3 N. PLOTTED= 106

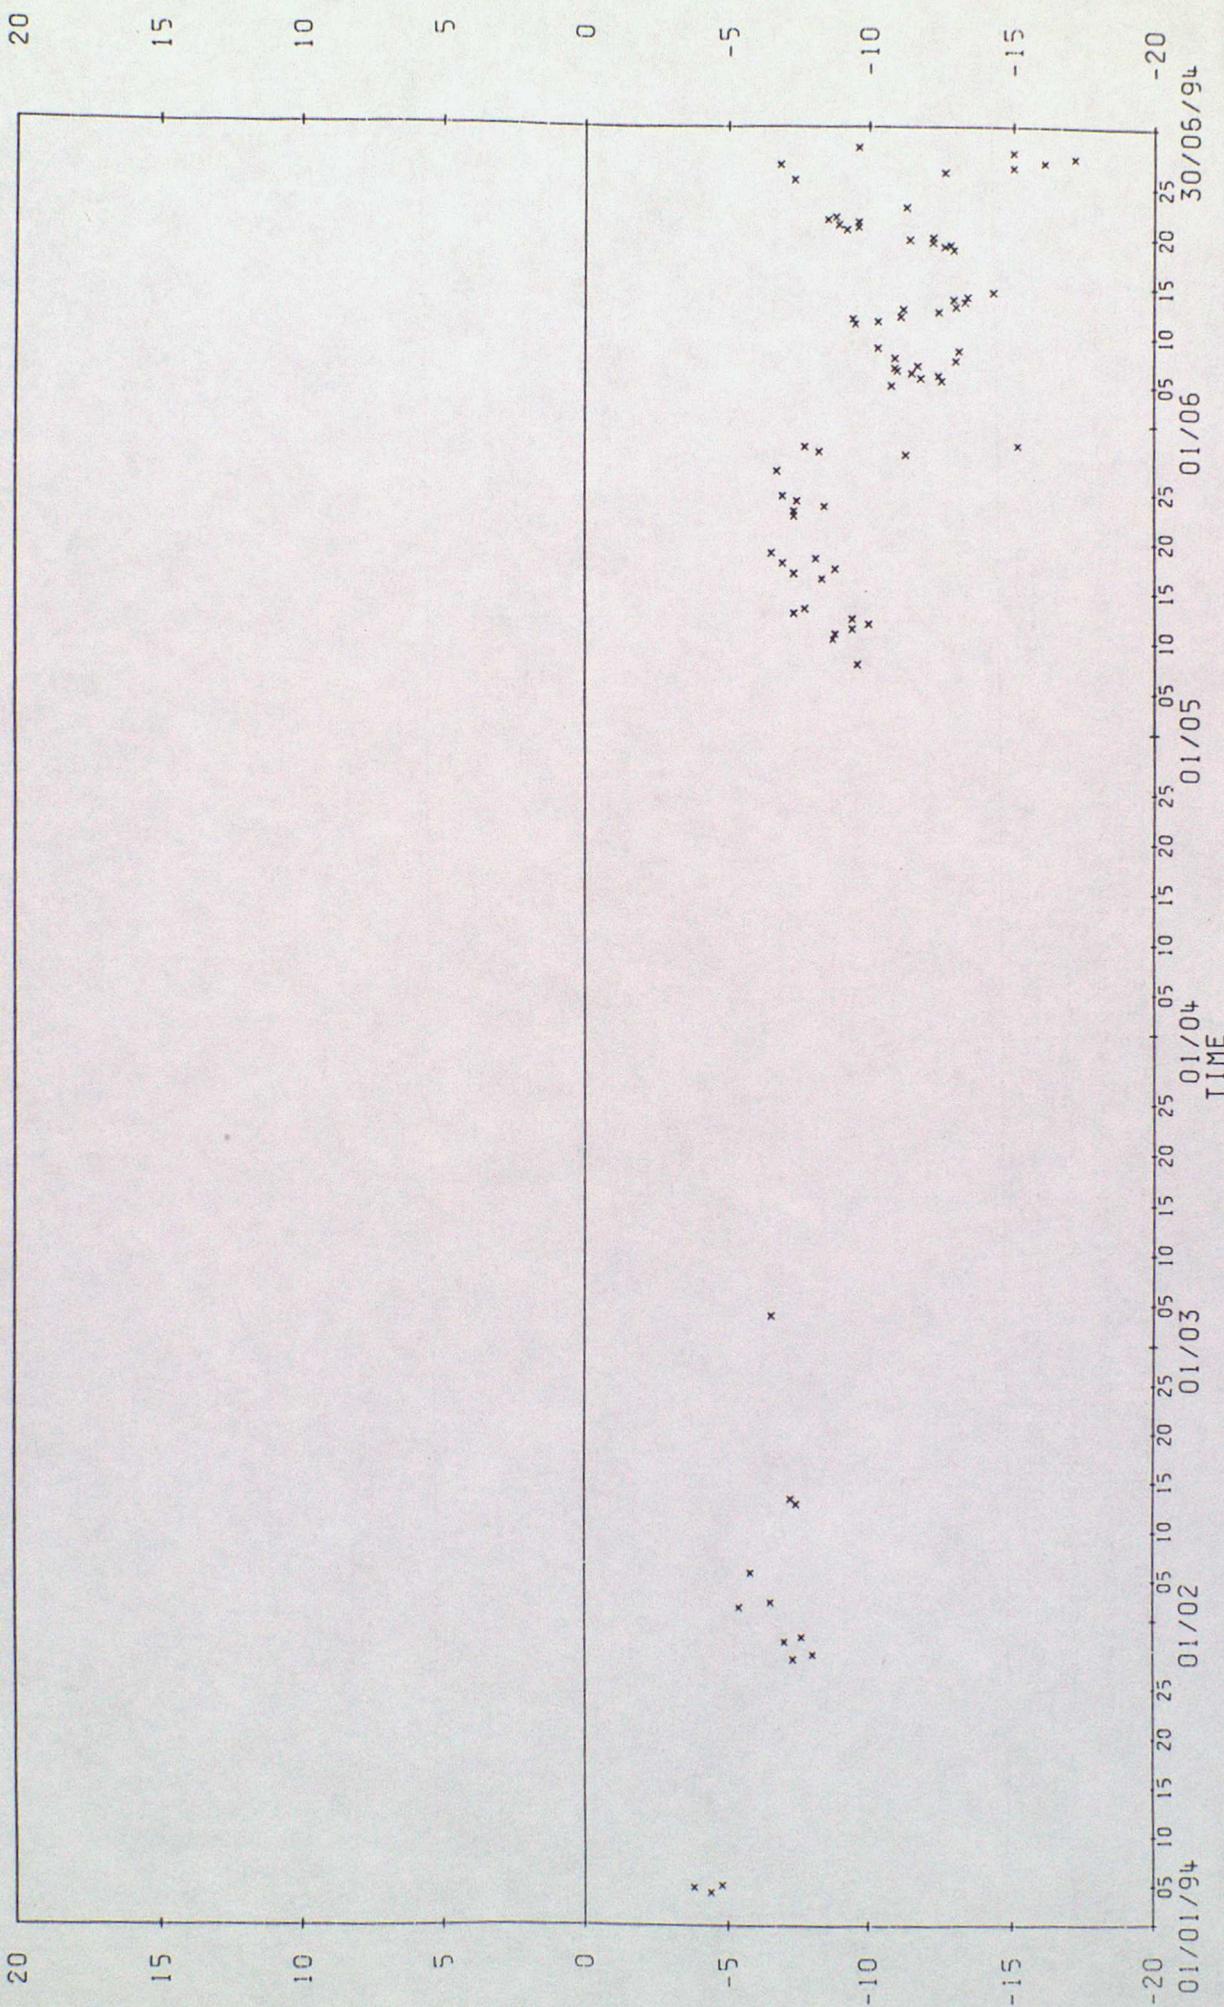

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: EUAF
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 69

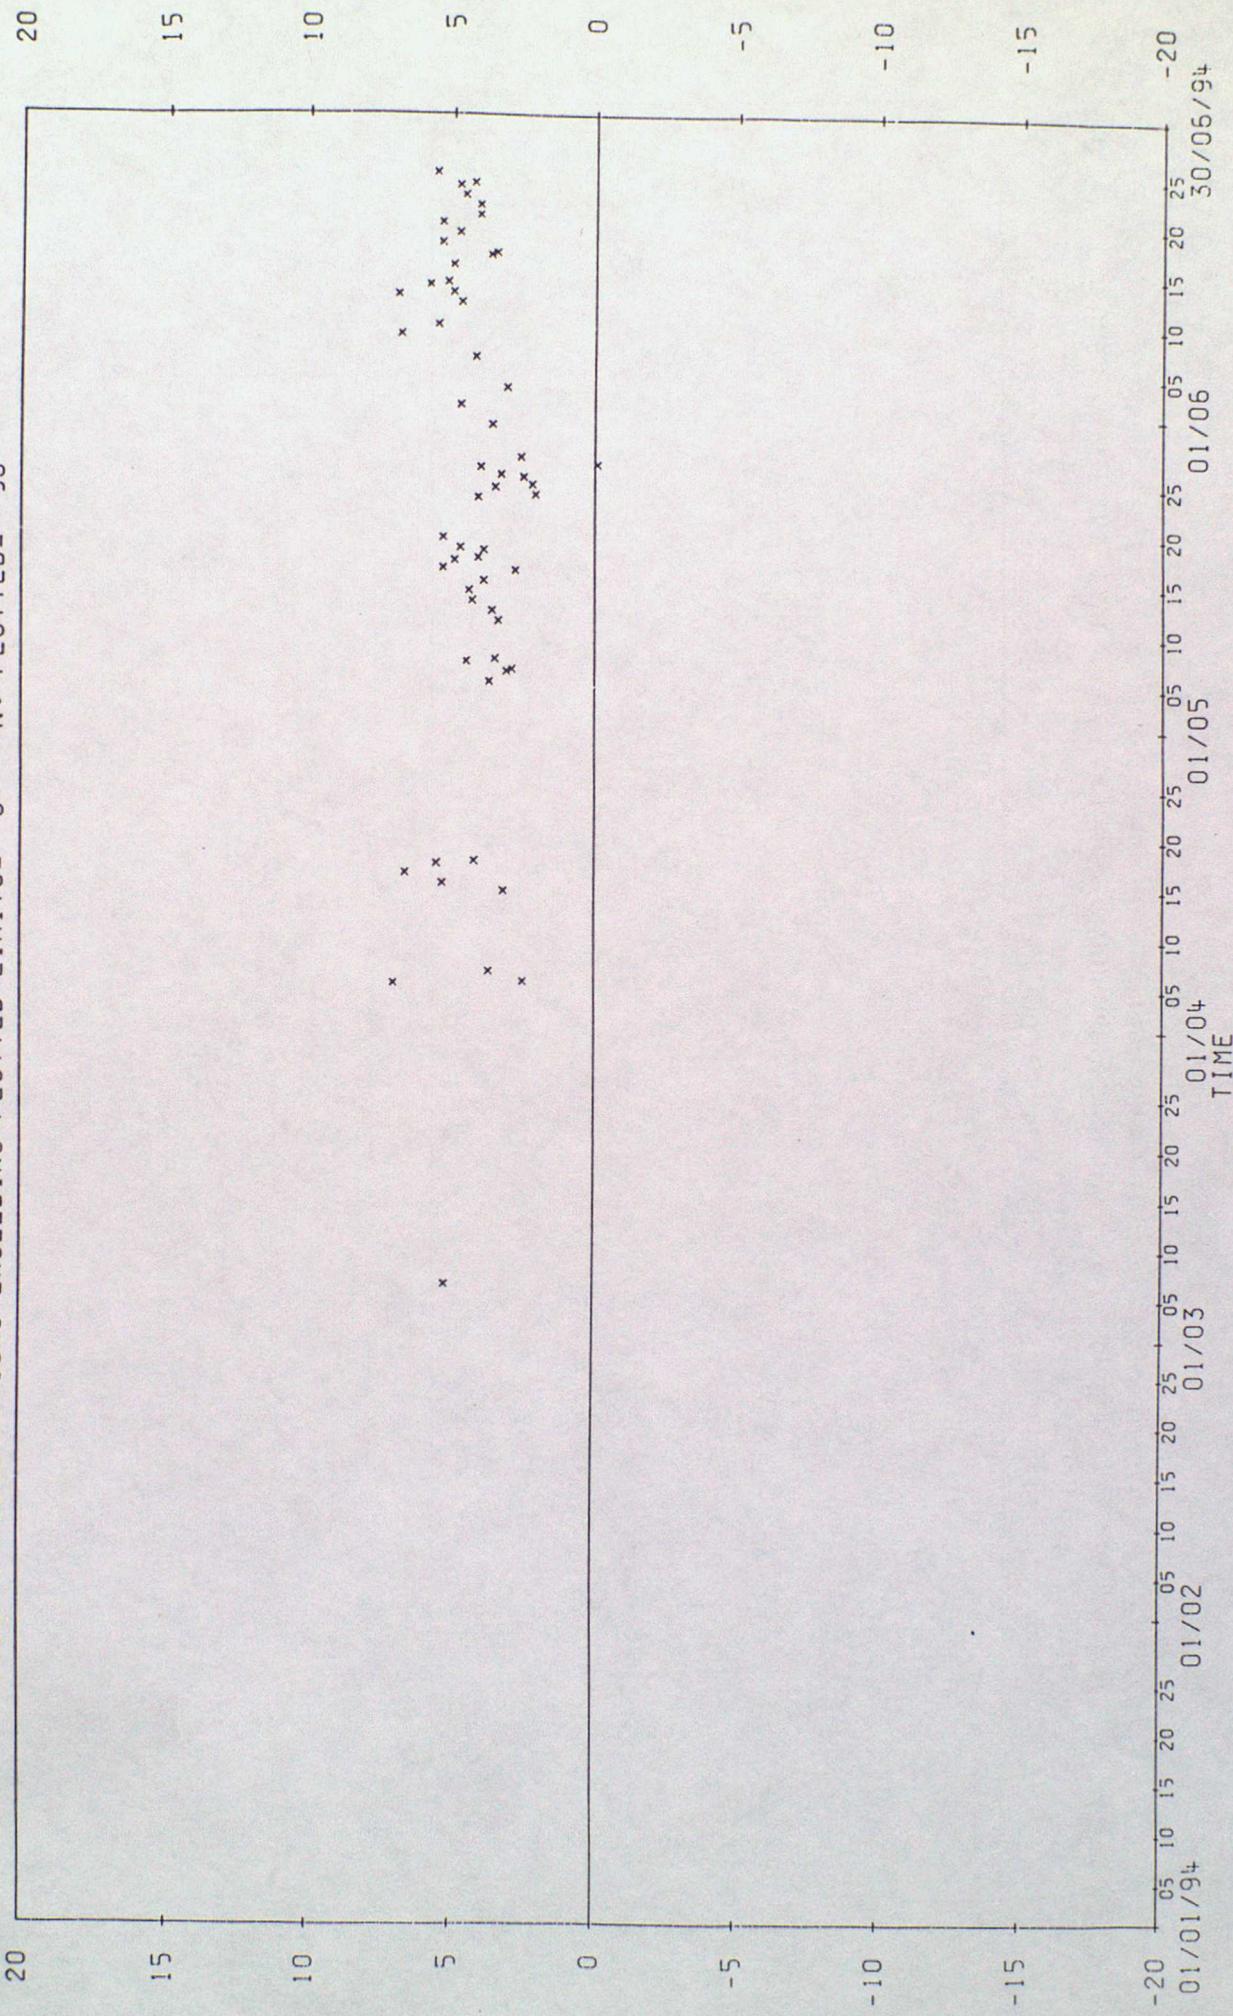

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: KRHZ
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 2 N. PLOTTED= 52

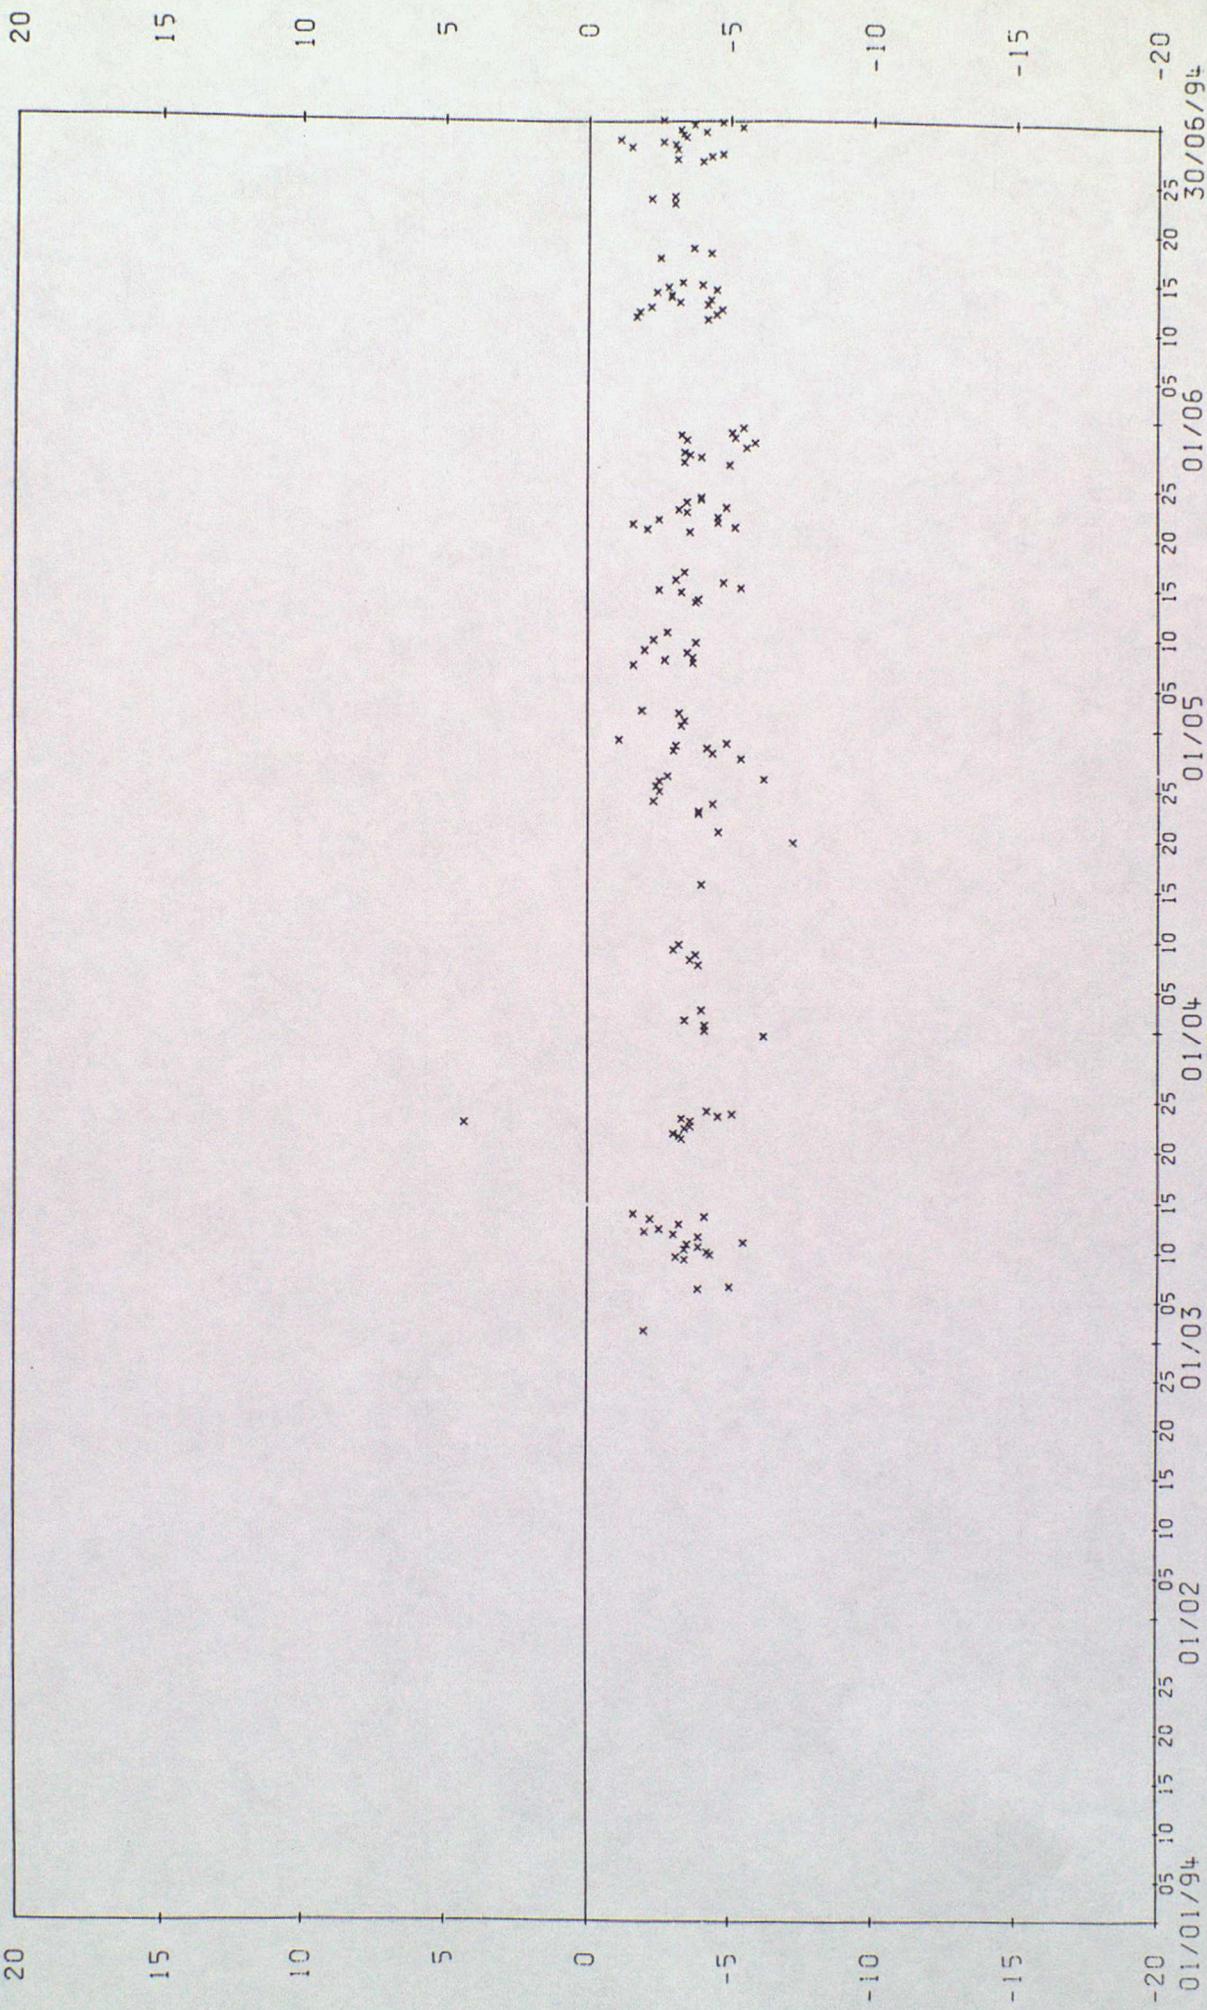

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: KXDB
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 81

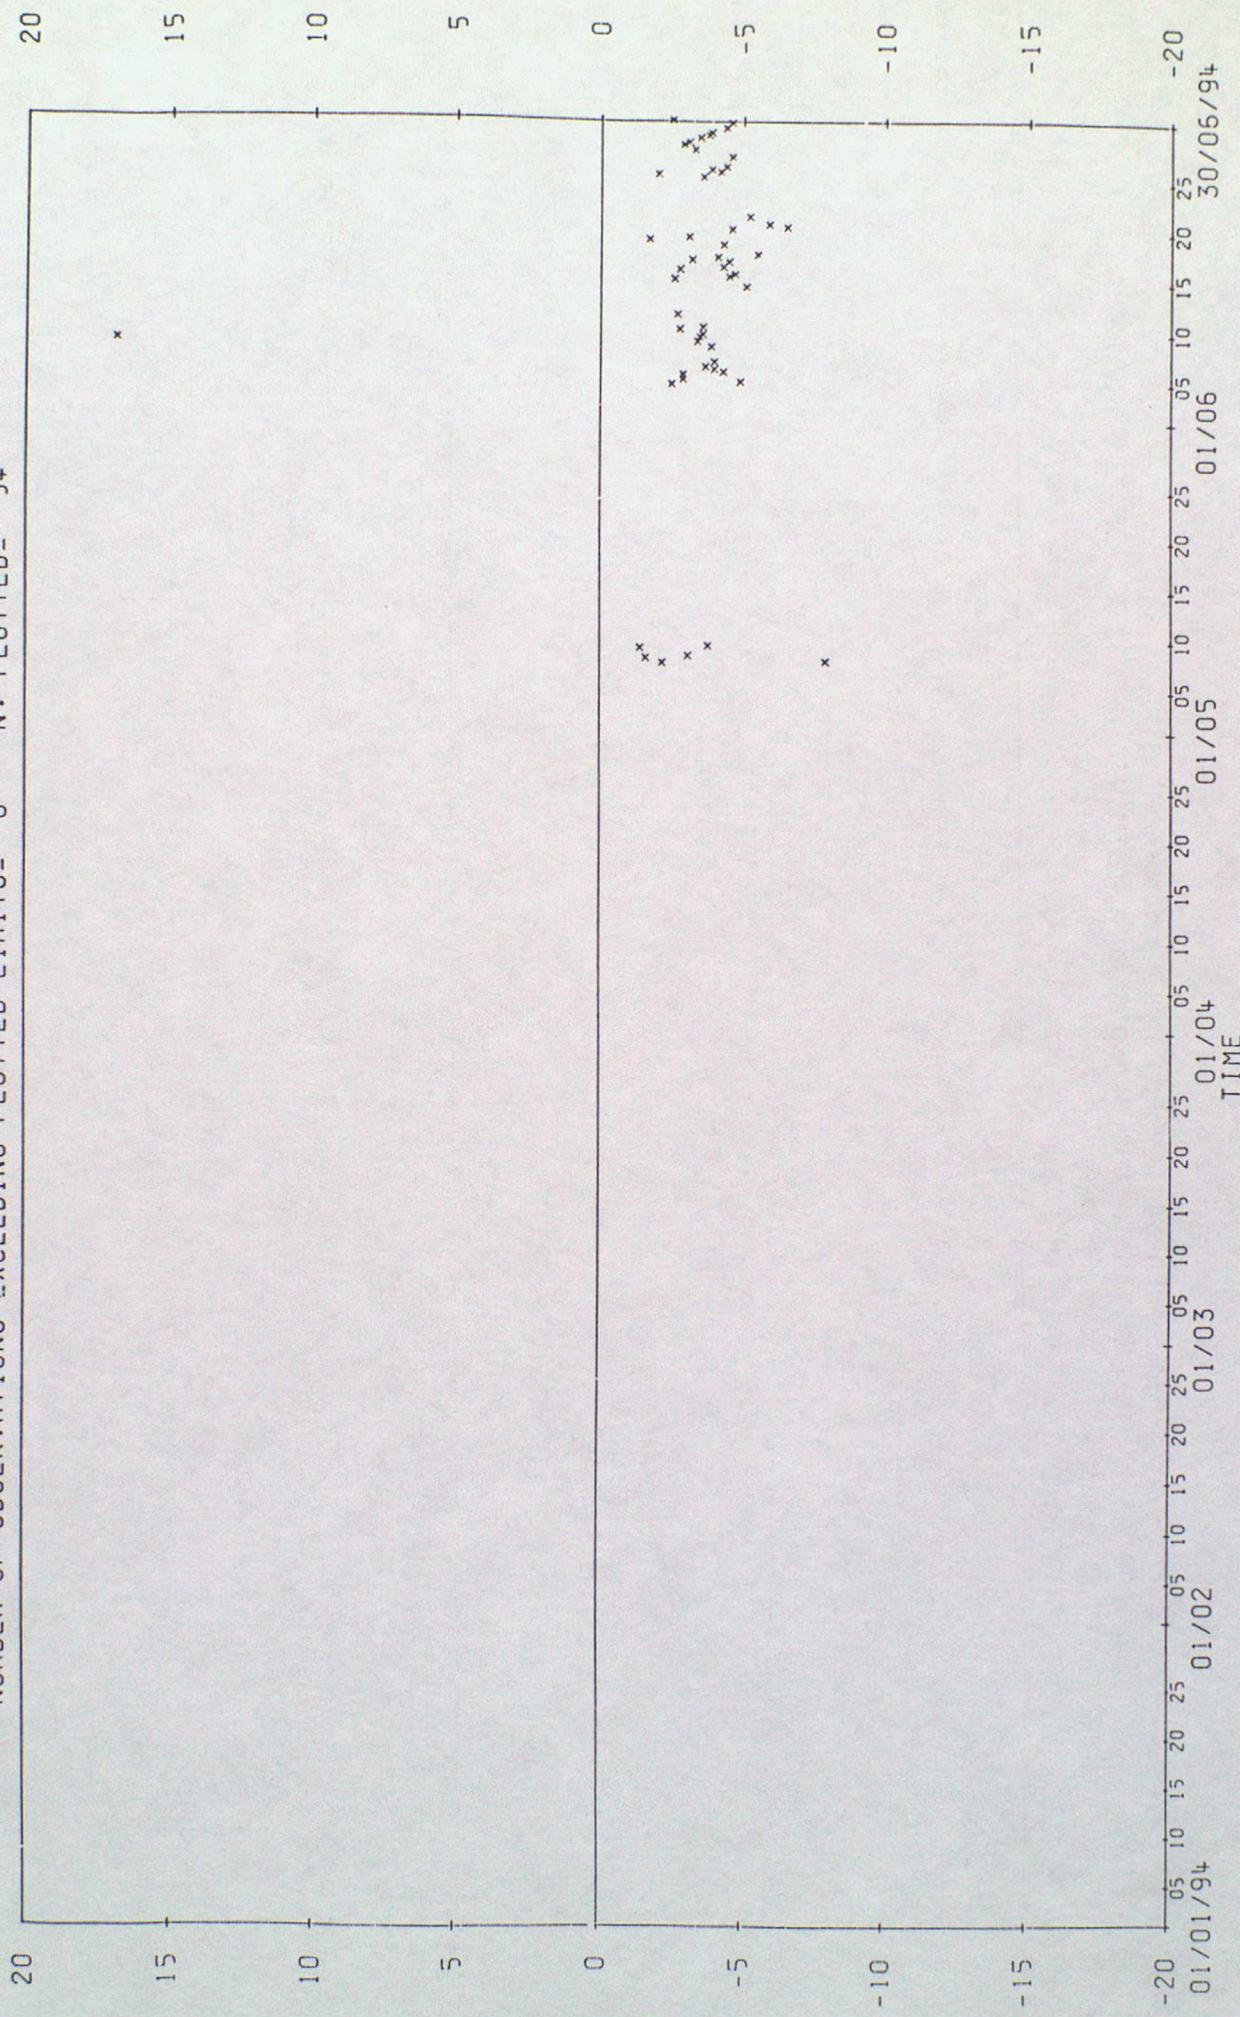

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: LAMT₄
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 58

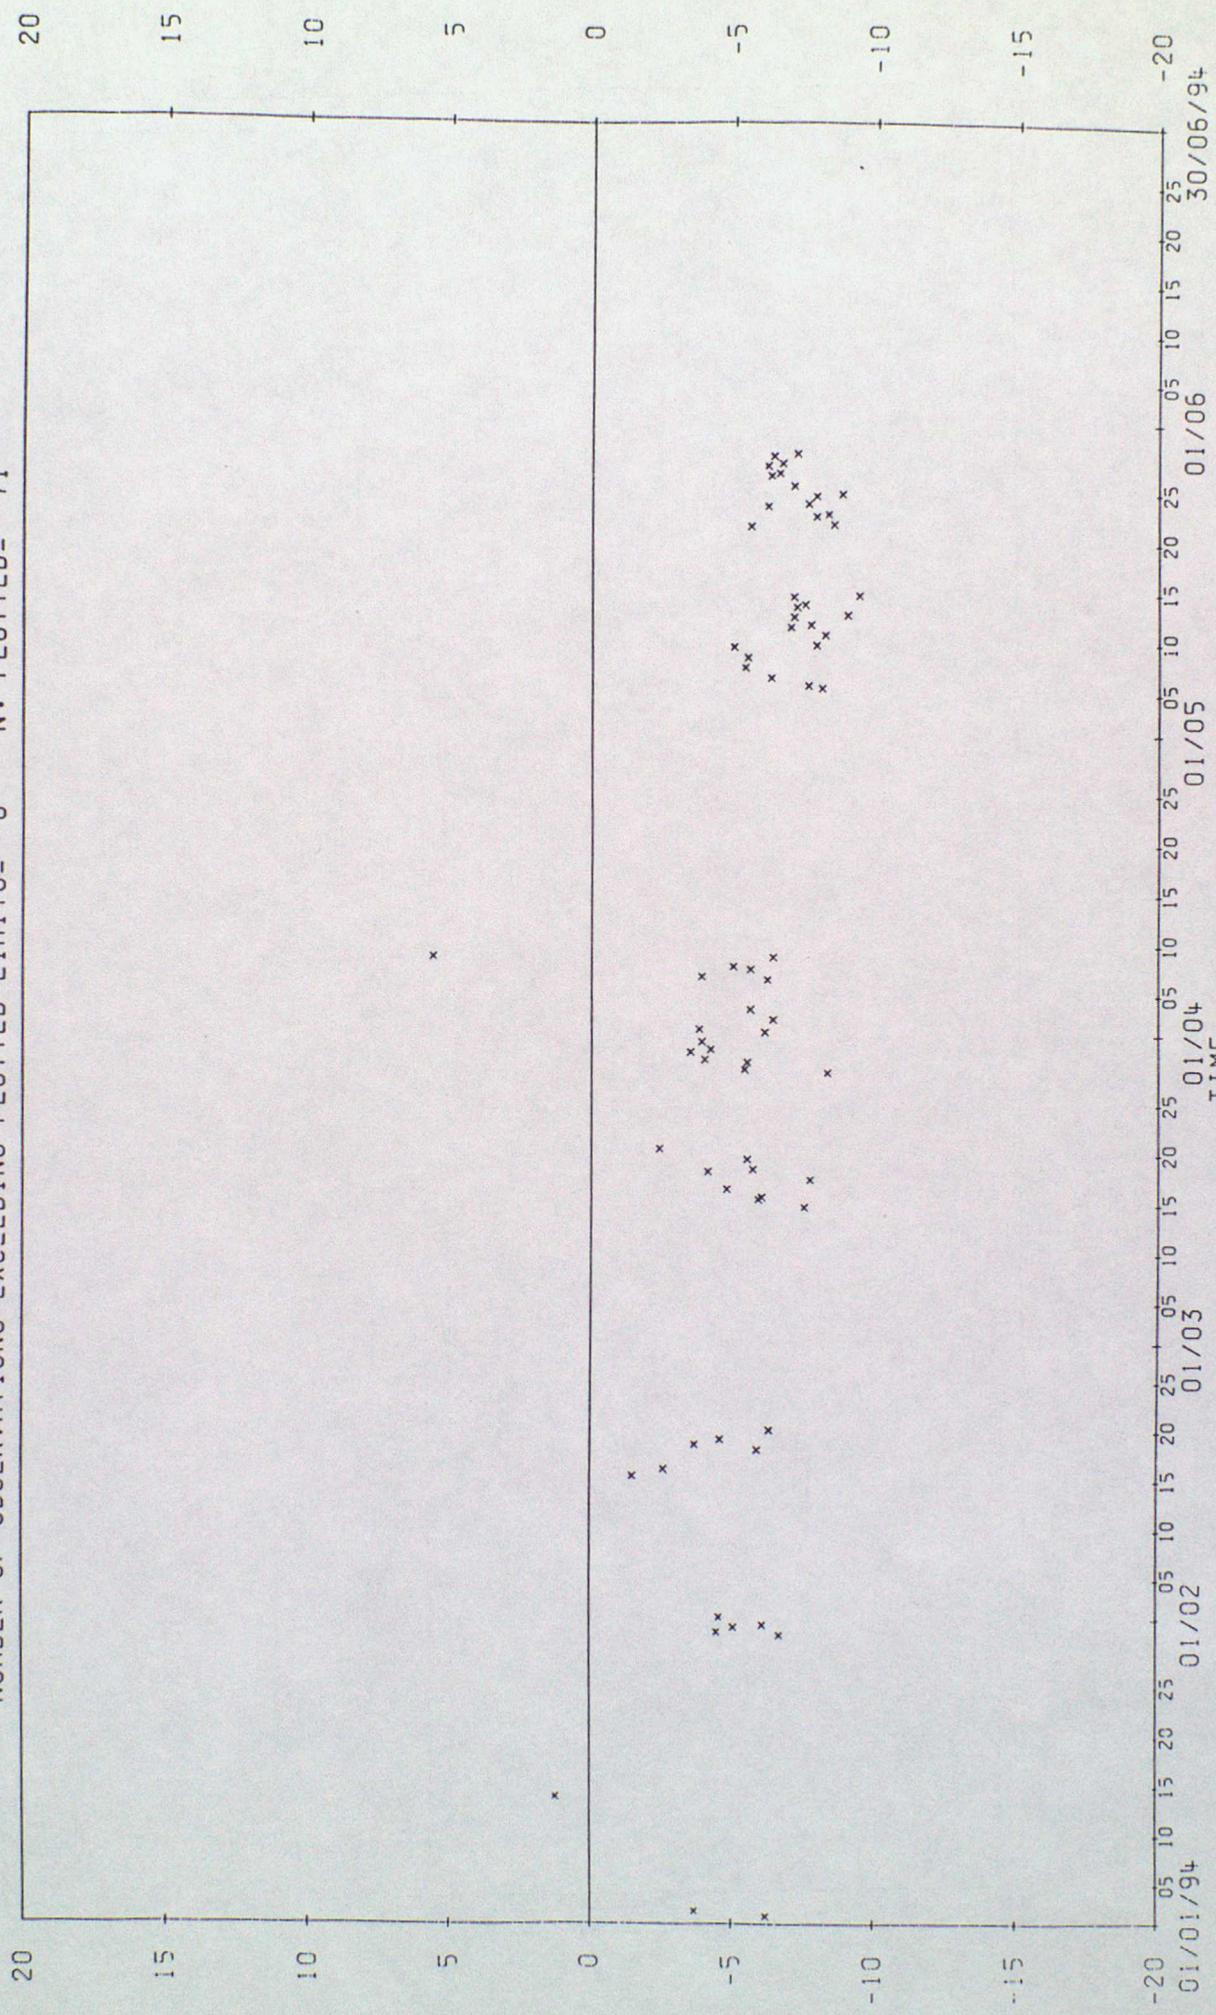

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: PEMA
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 144

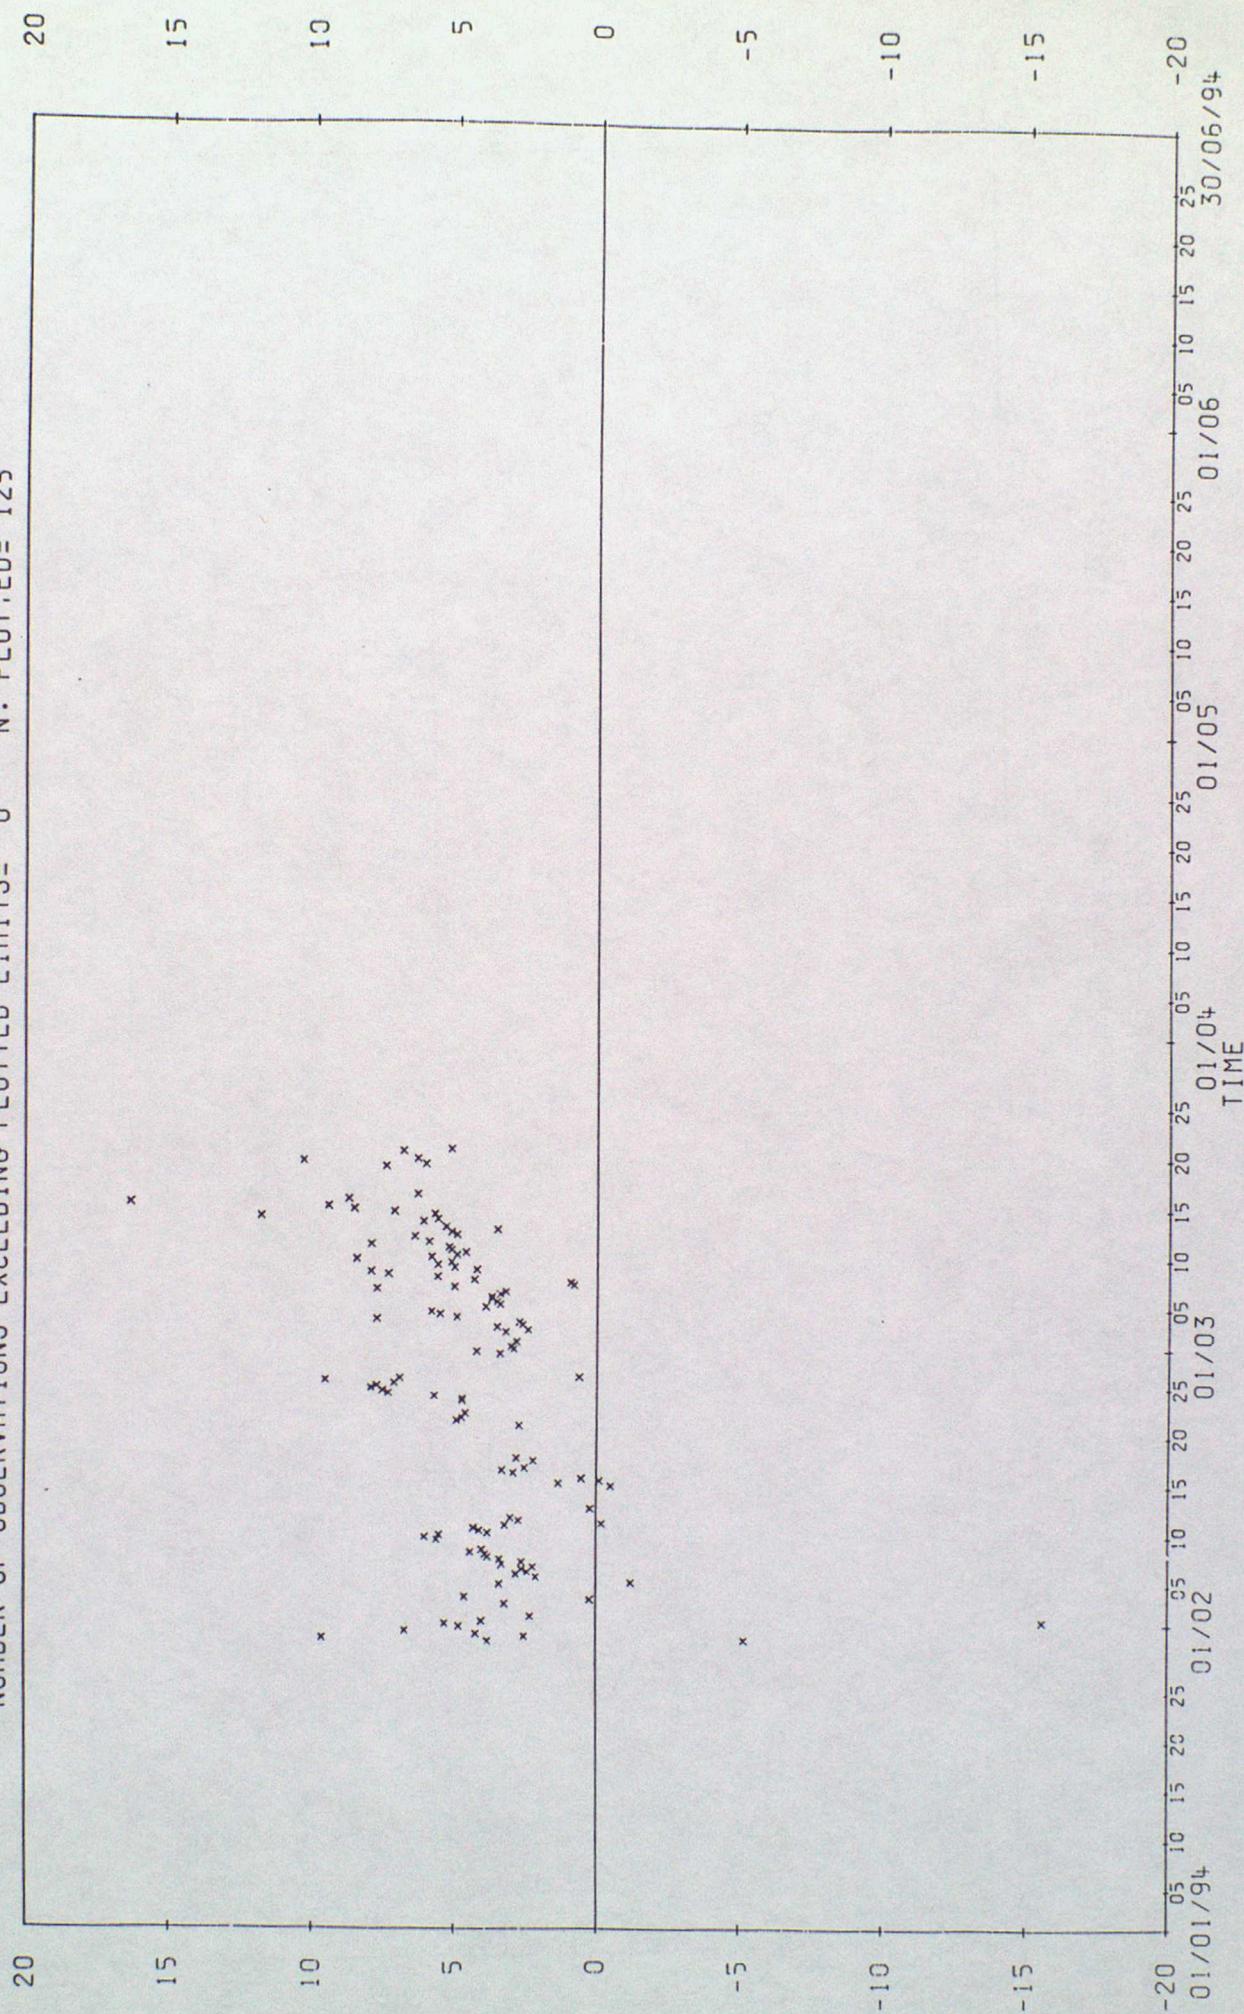

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: PENQ
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 54

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: P3ZL4 0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 71

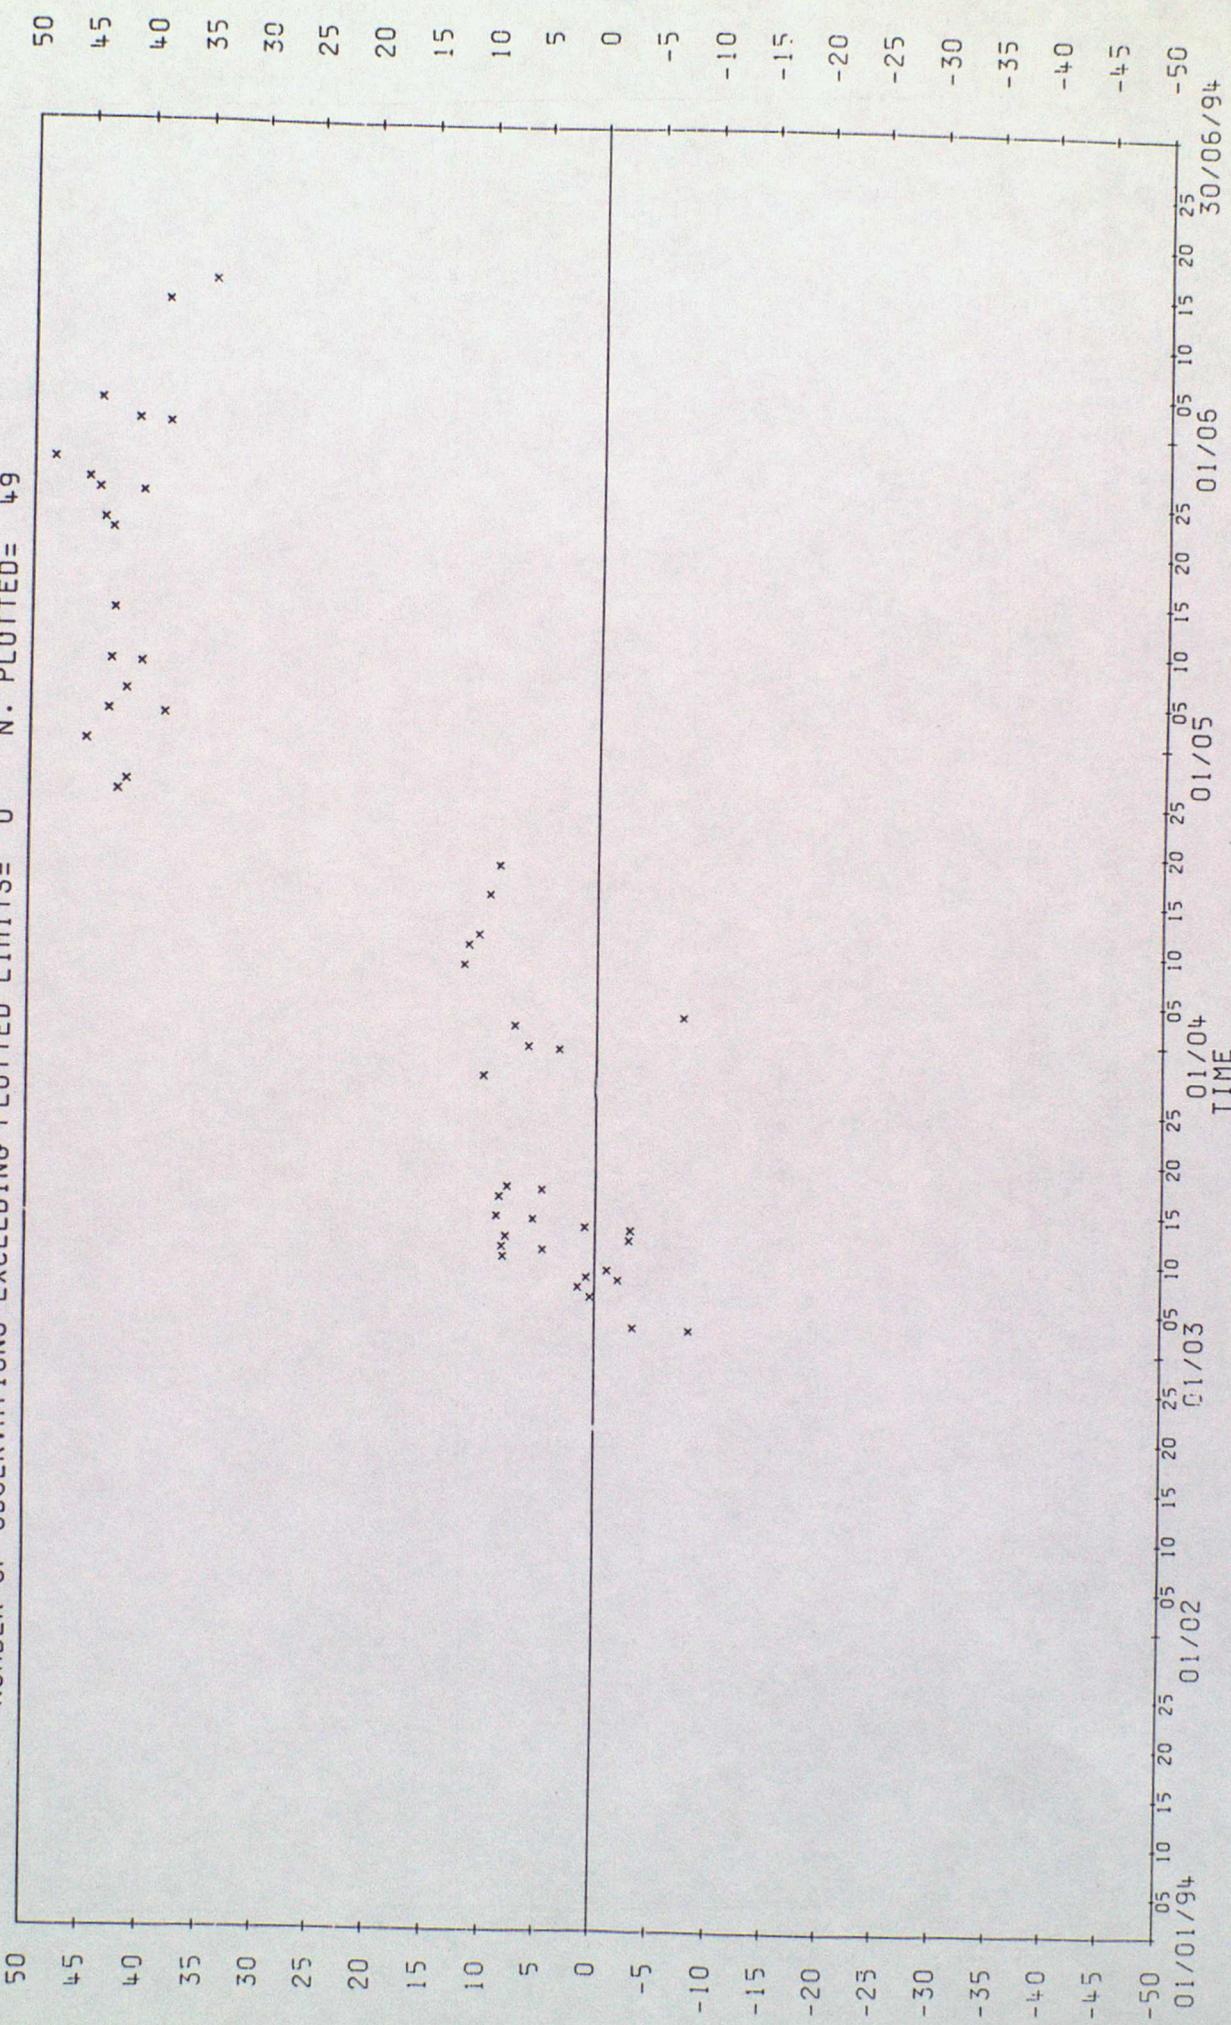

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: SCYN
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 125

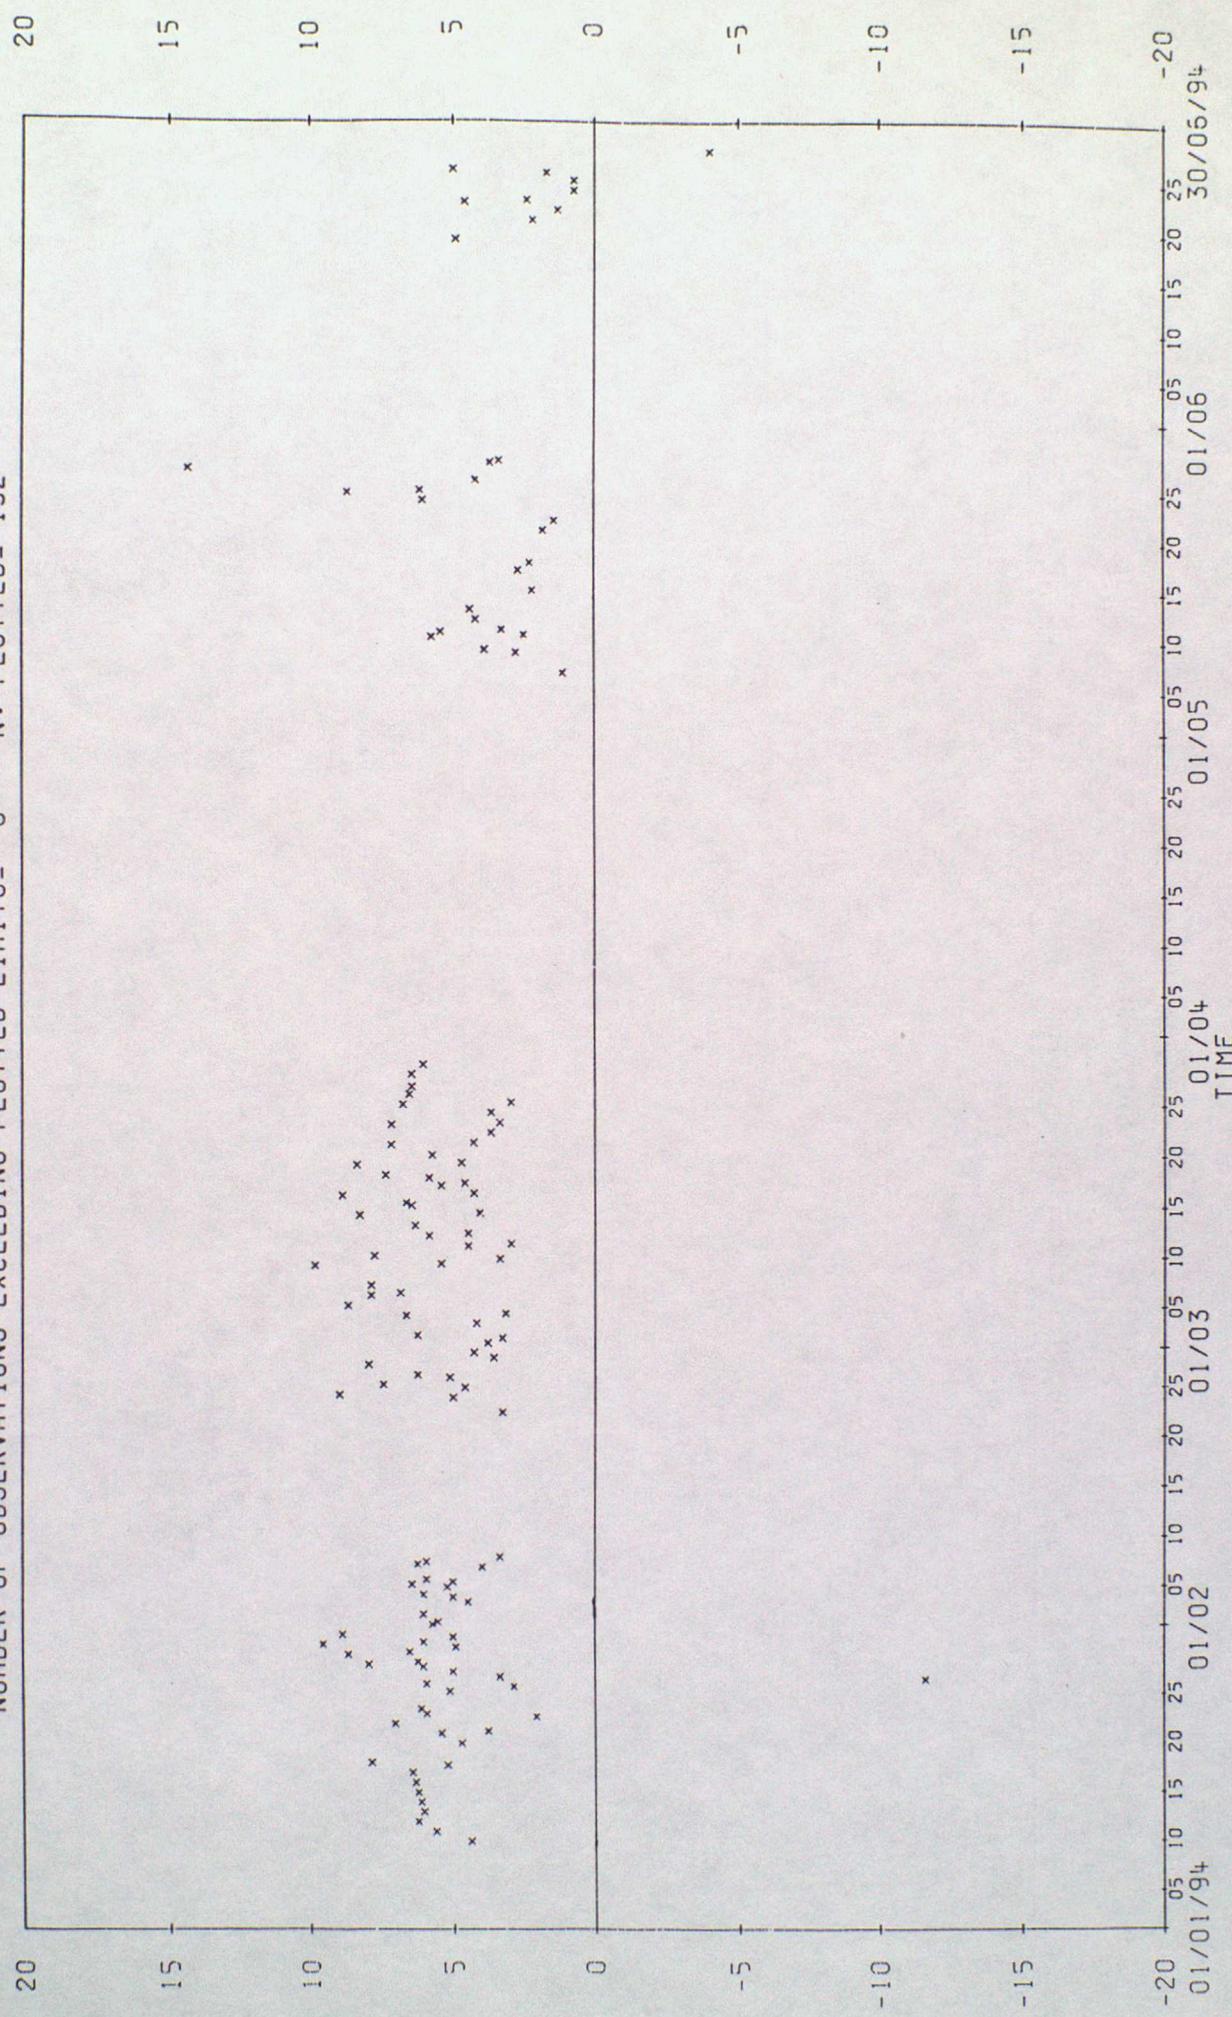

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UBHT
0-B

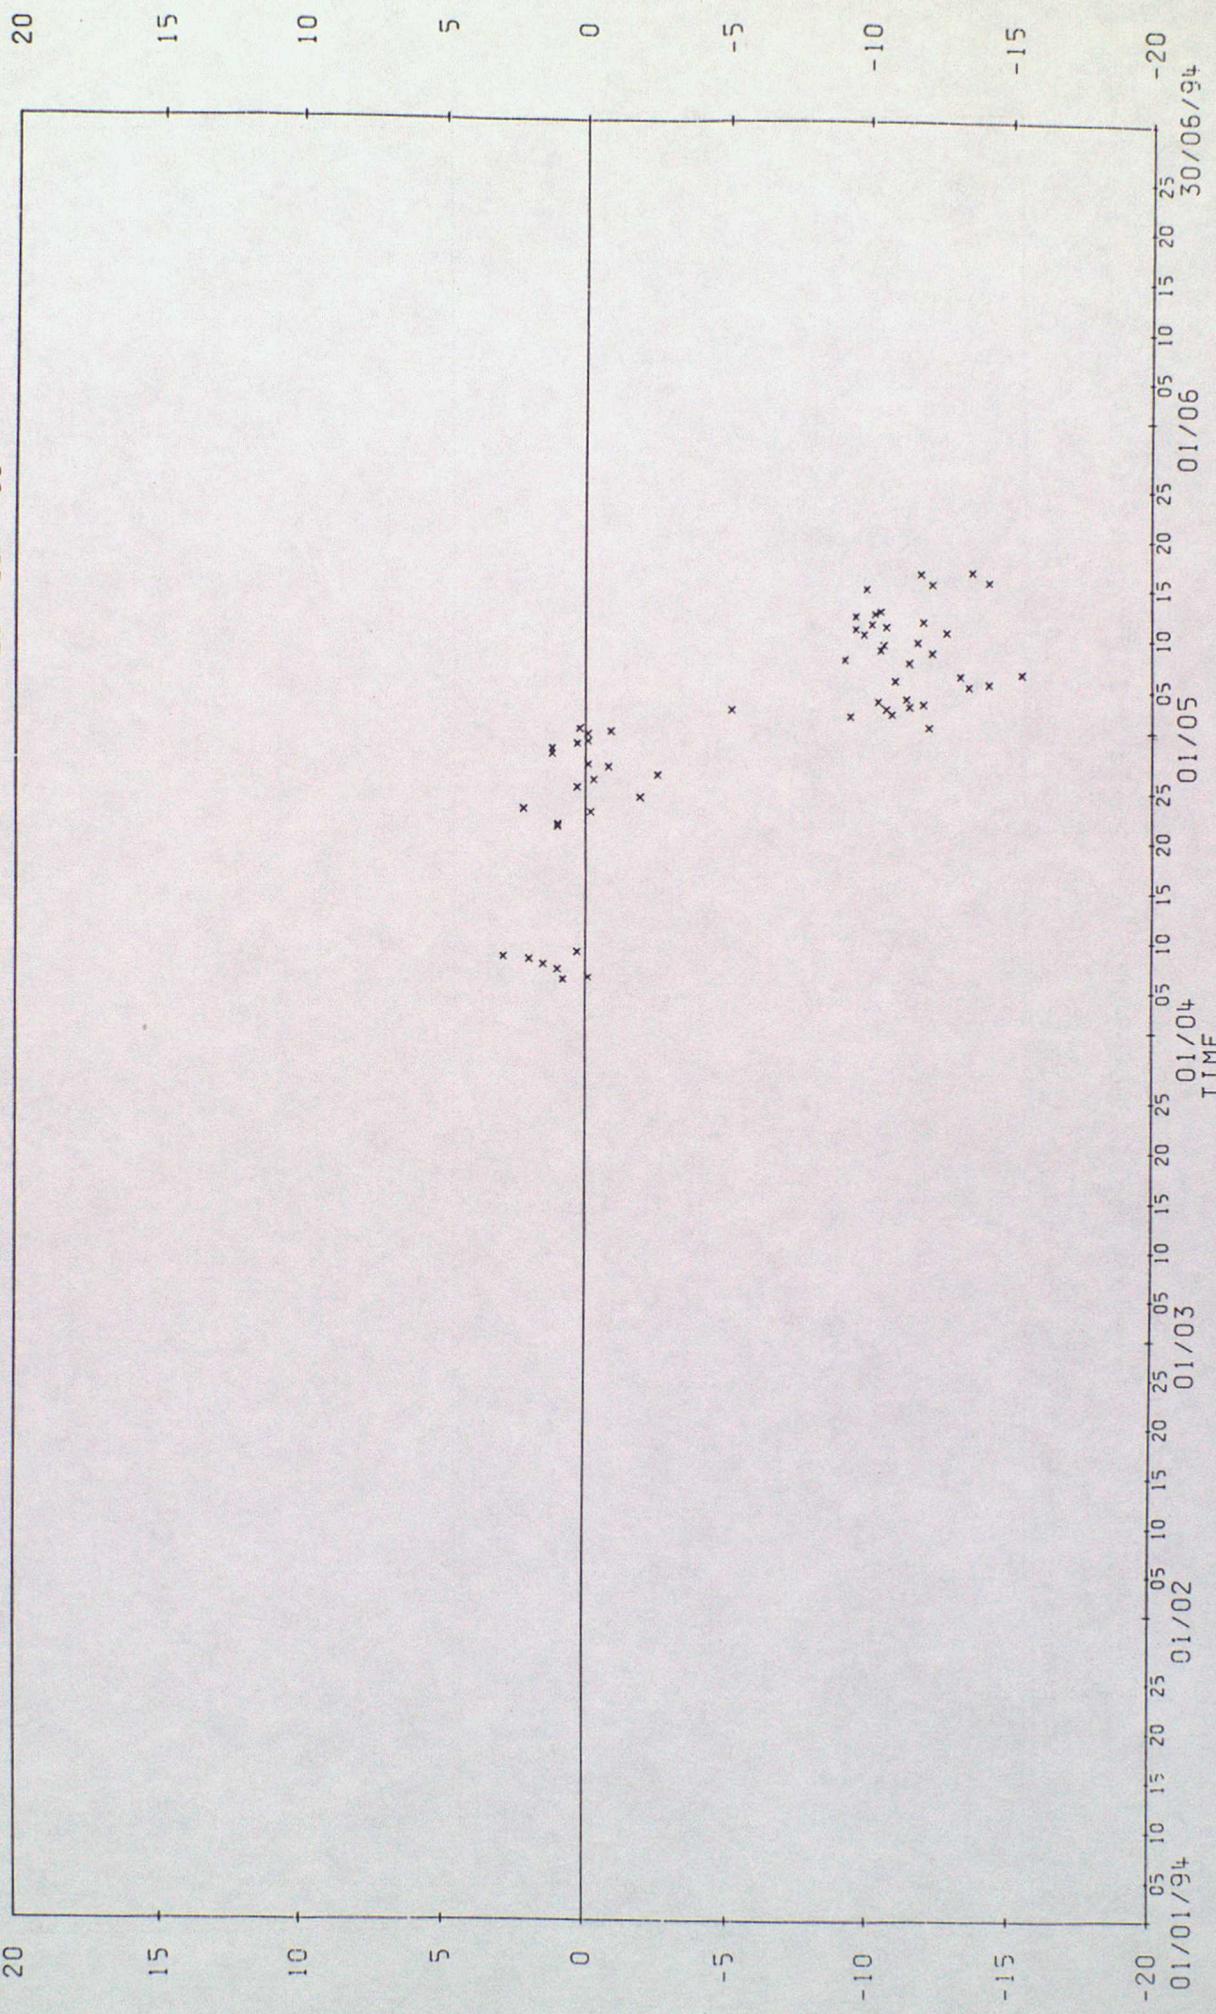

VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 49

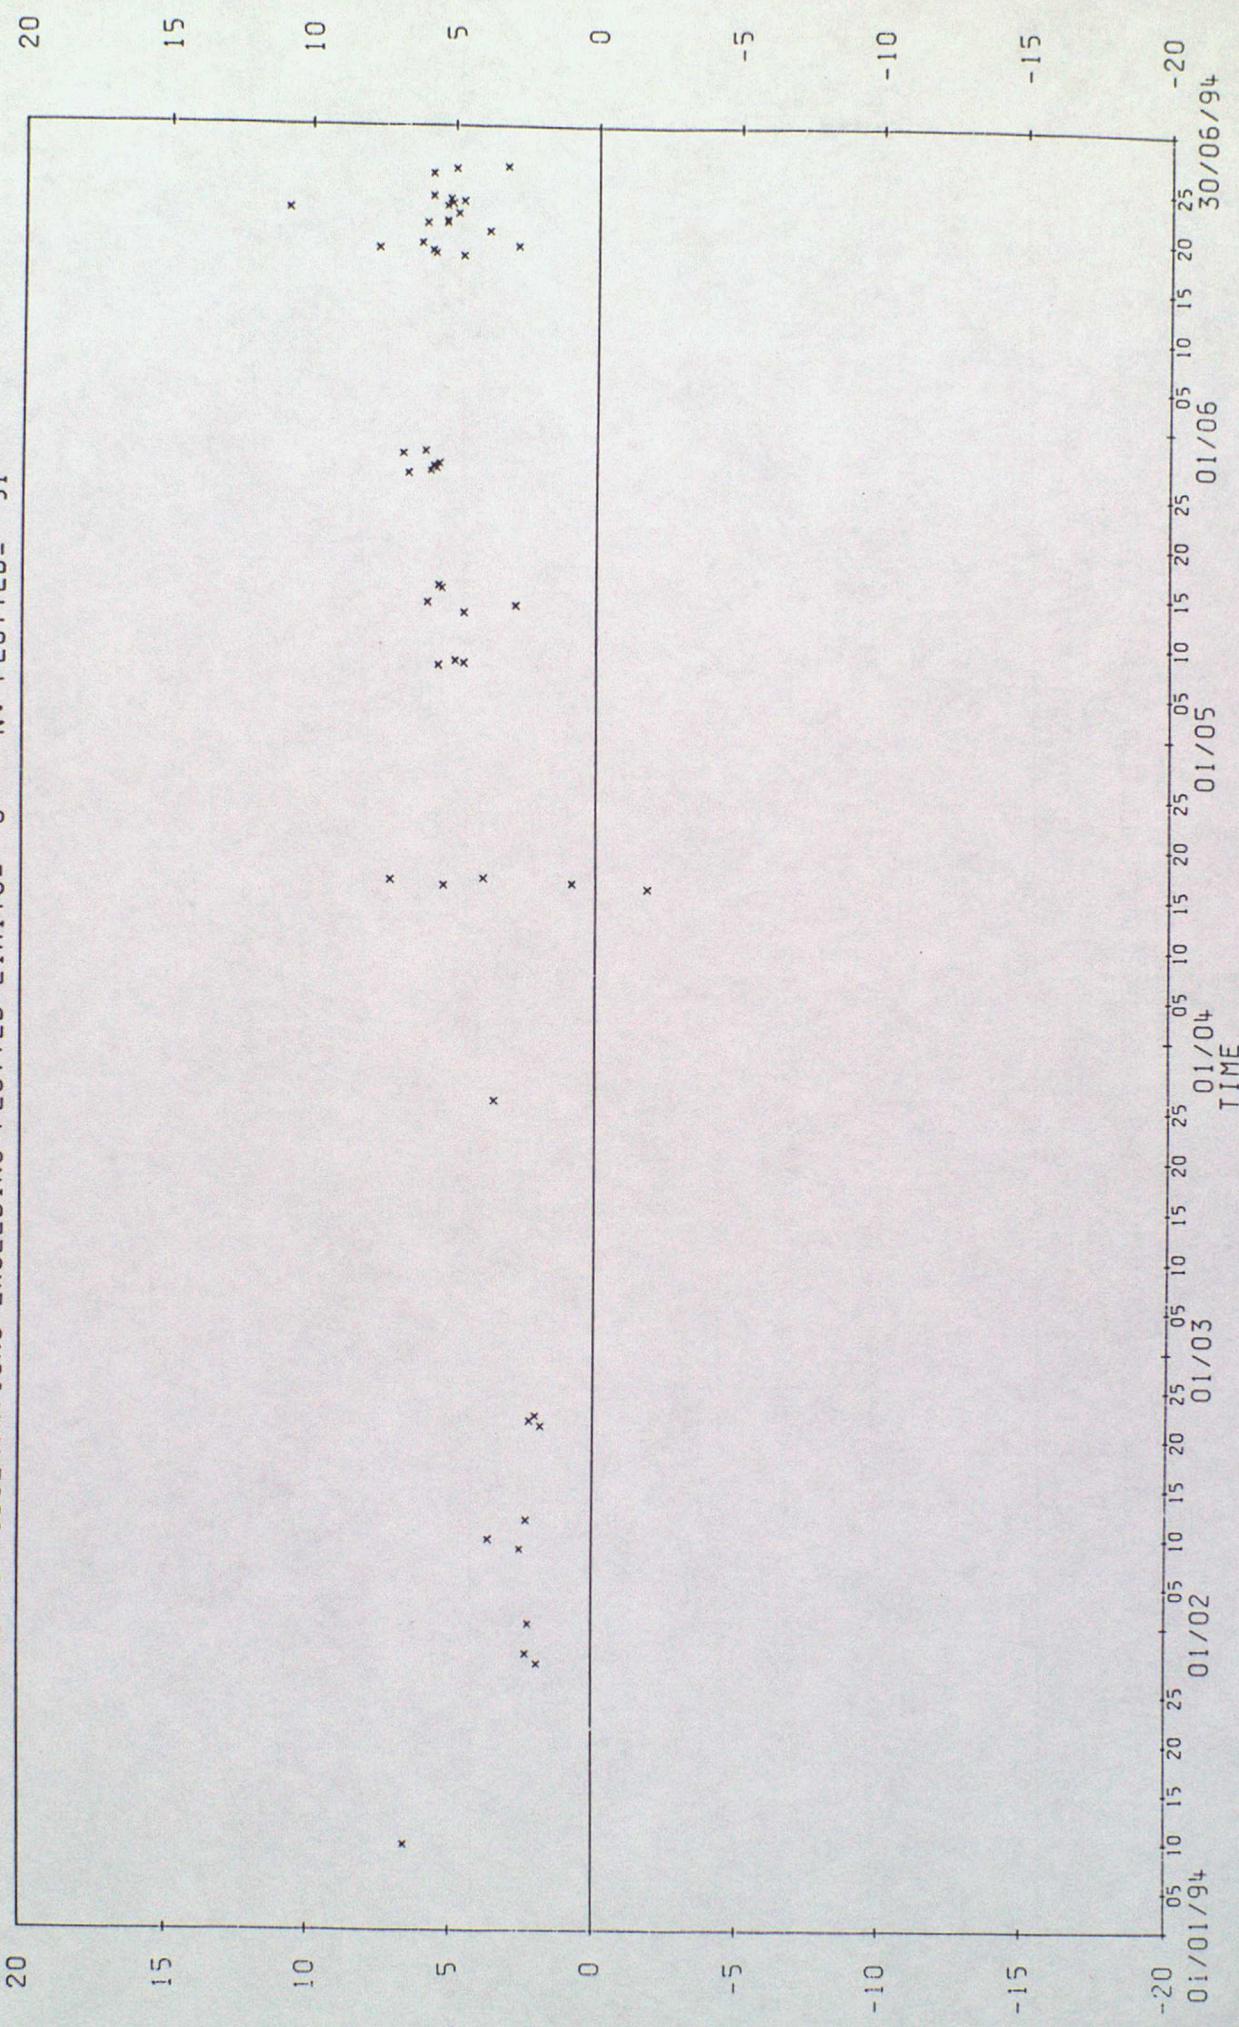

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UHUN
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 132

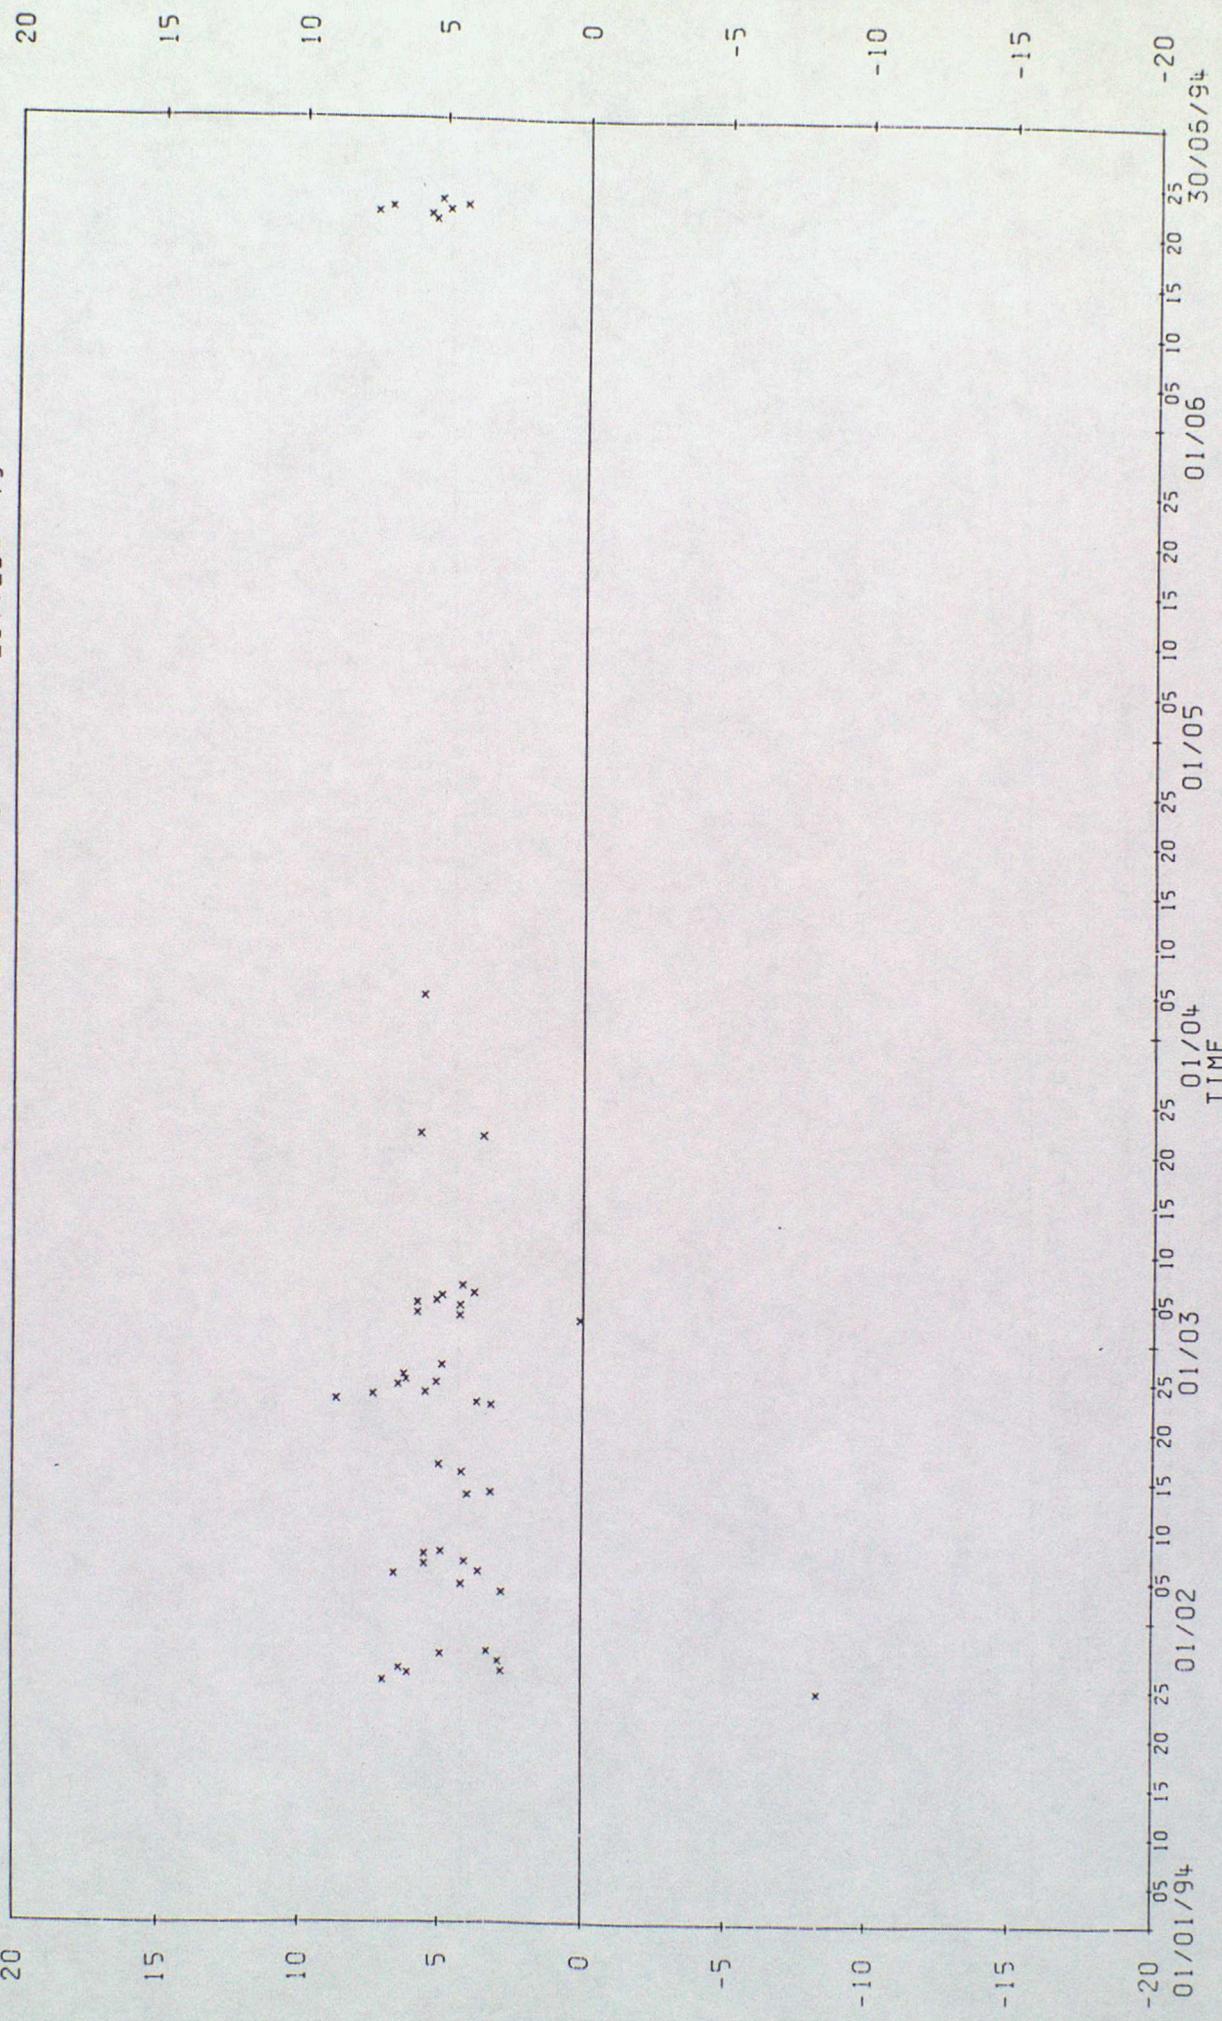

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UHZK
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 58

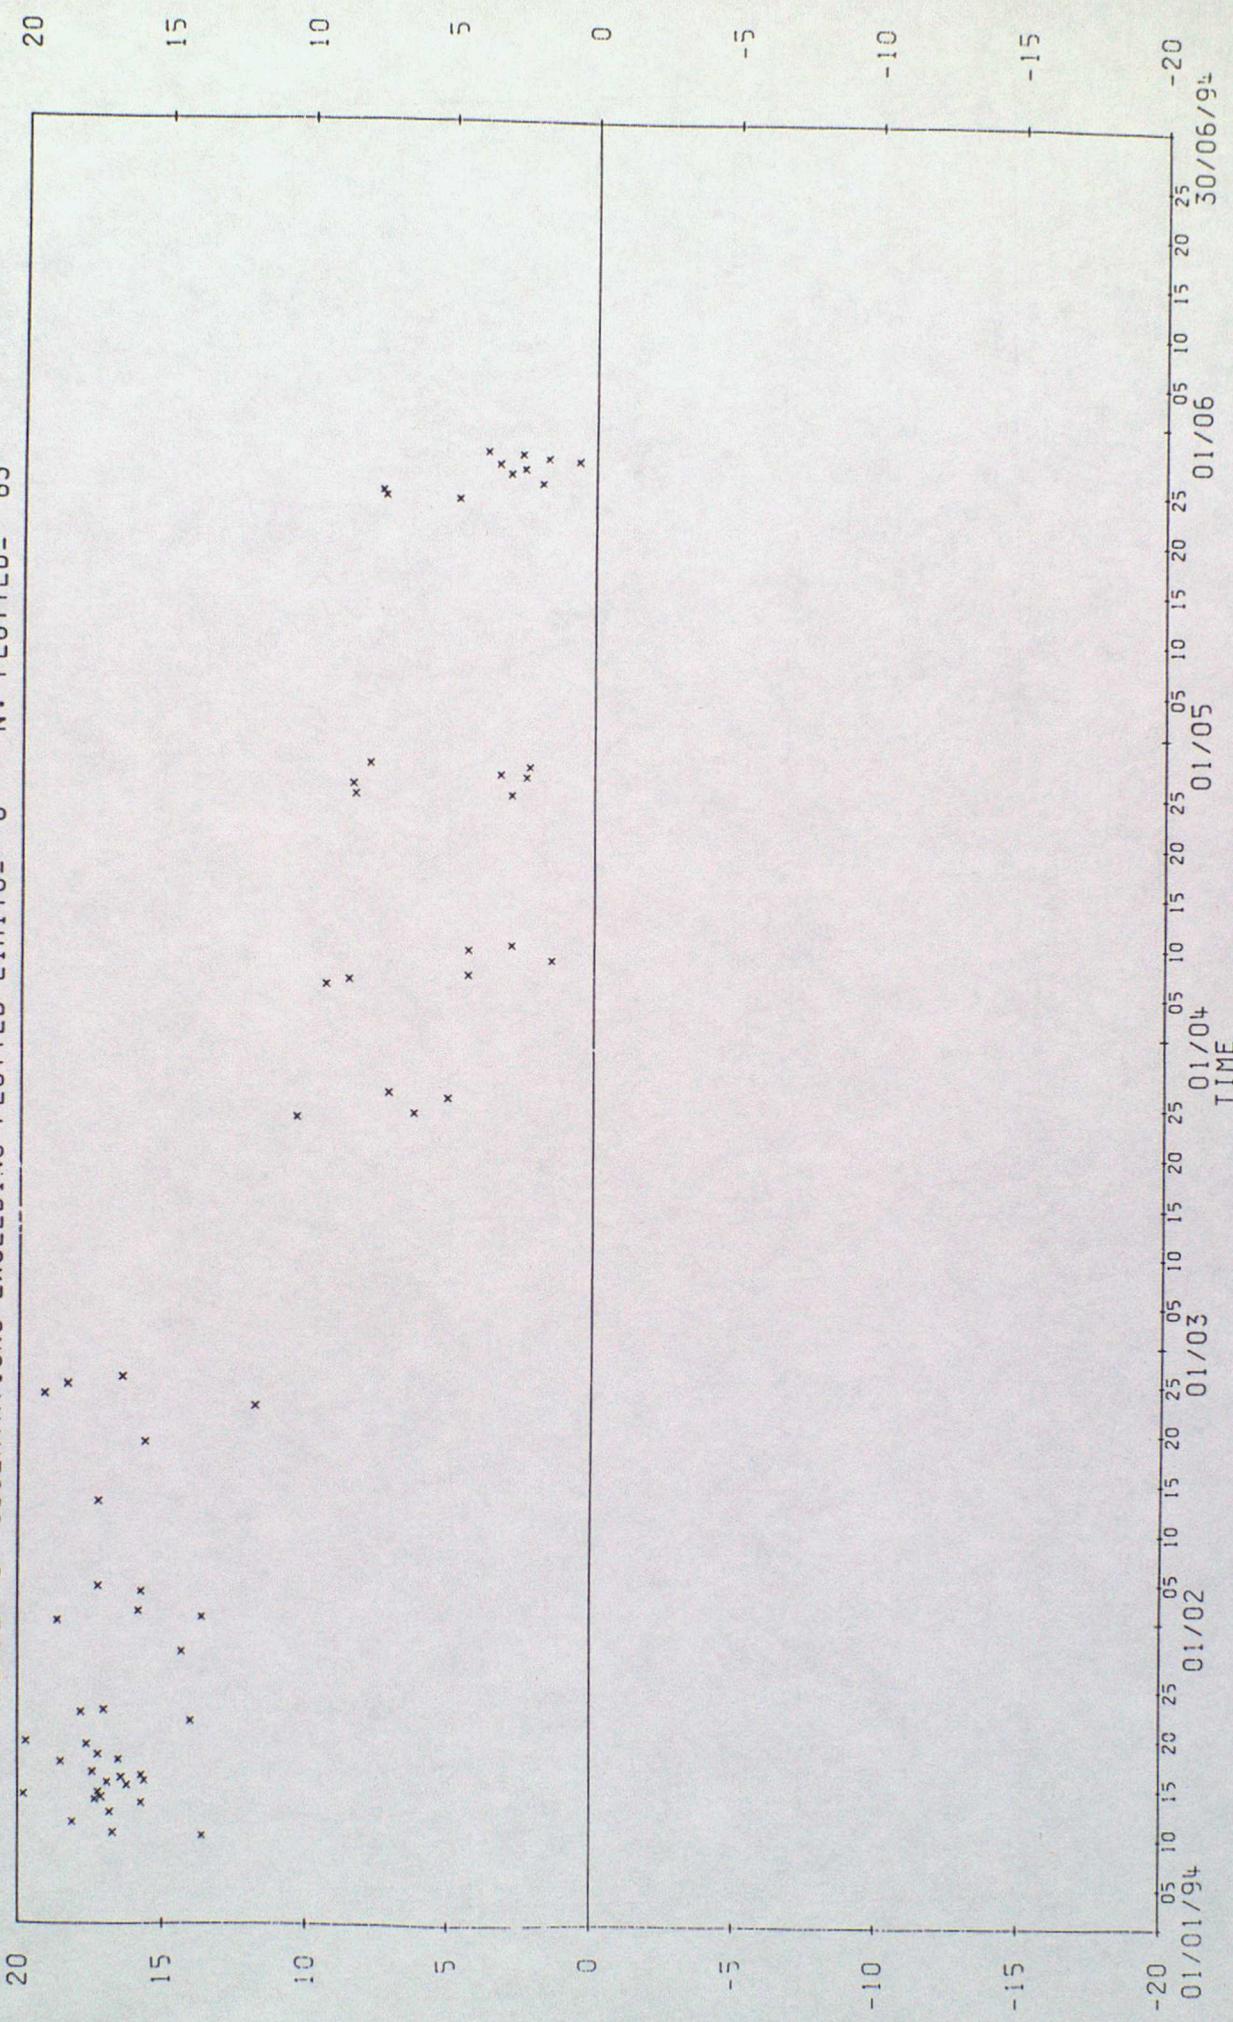

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UKTV
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 51

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
0-B TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UNWJ
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 49

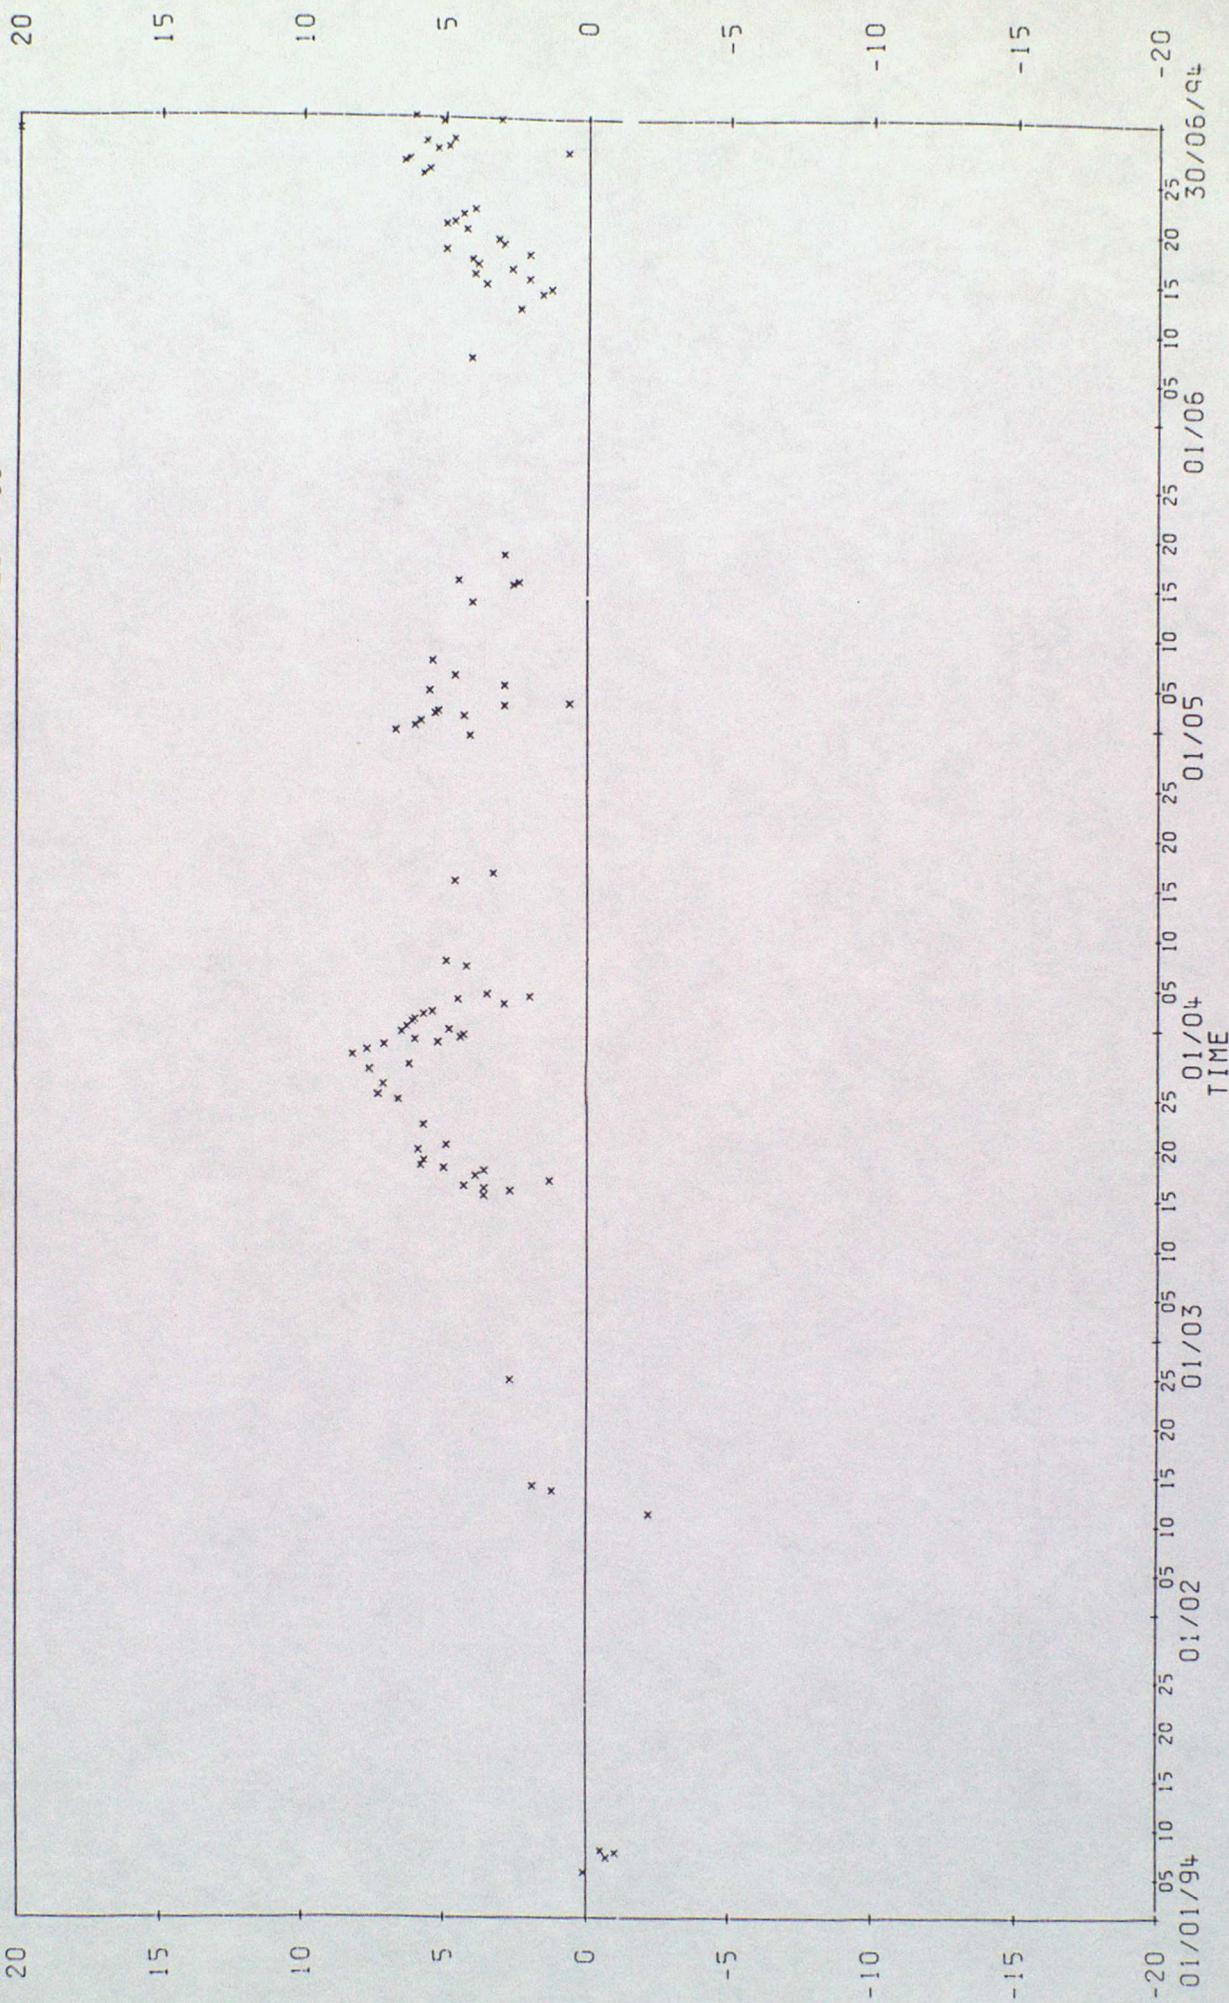

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UOVE
0-B
VARIABLE : MSLP IN UNITS OF HPA
NUMBER OF OBSERVATIONS EXCEEDING PLOTTED LIMITS= 0 N. PLOTTED= 63

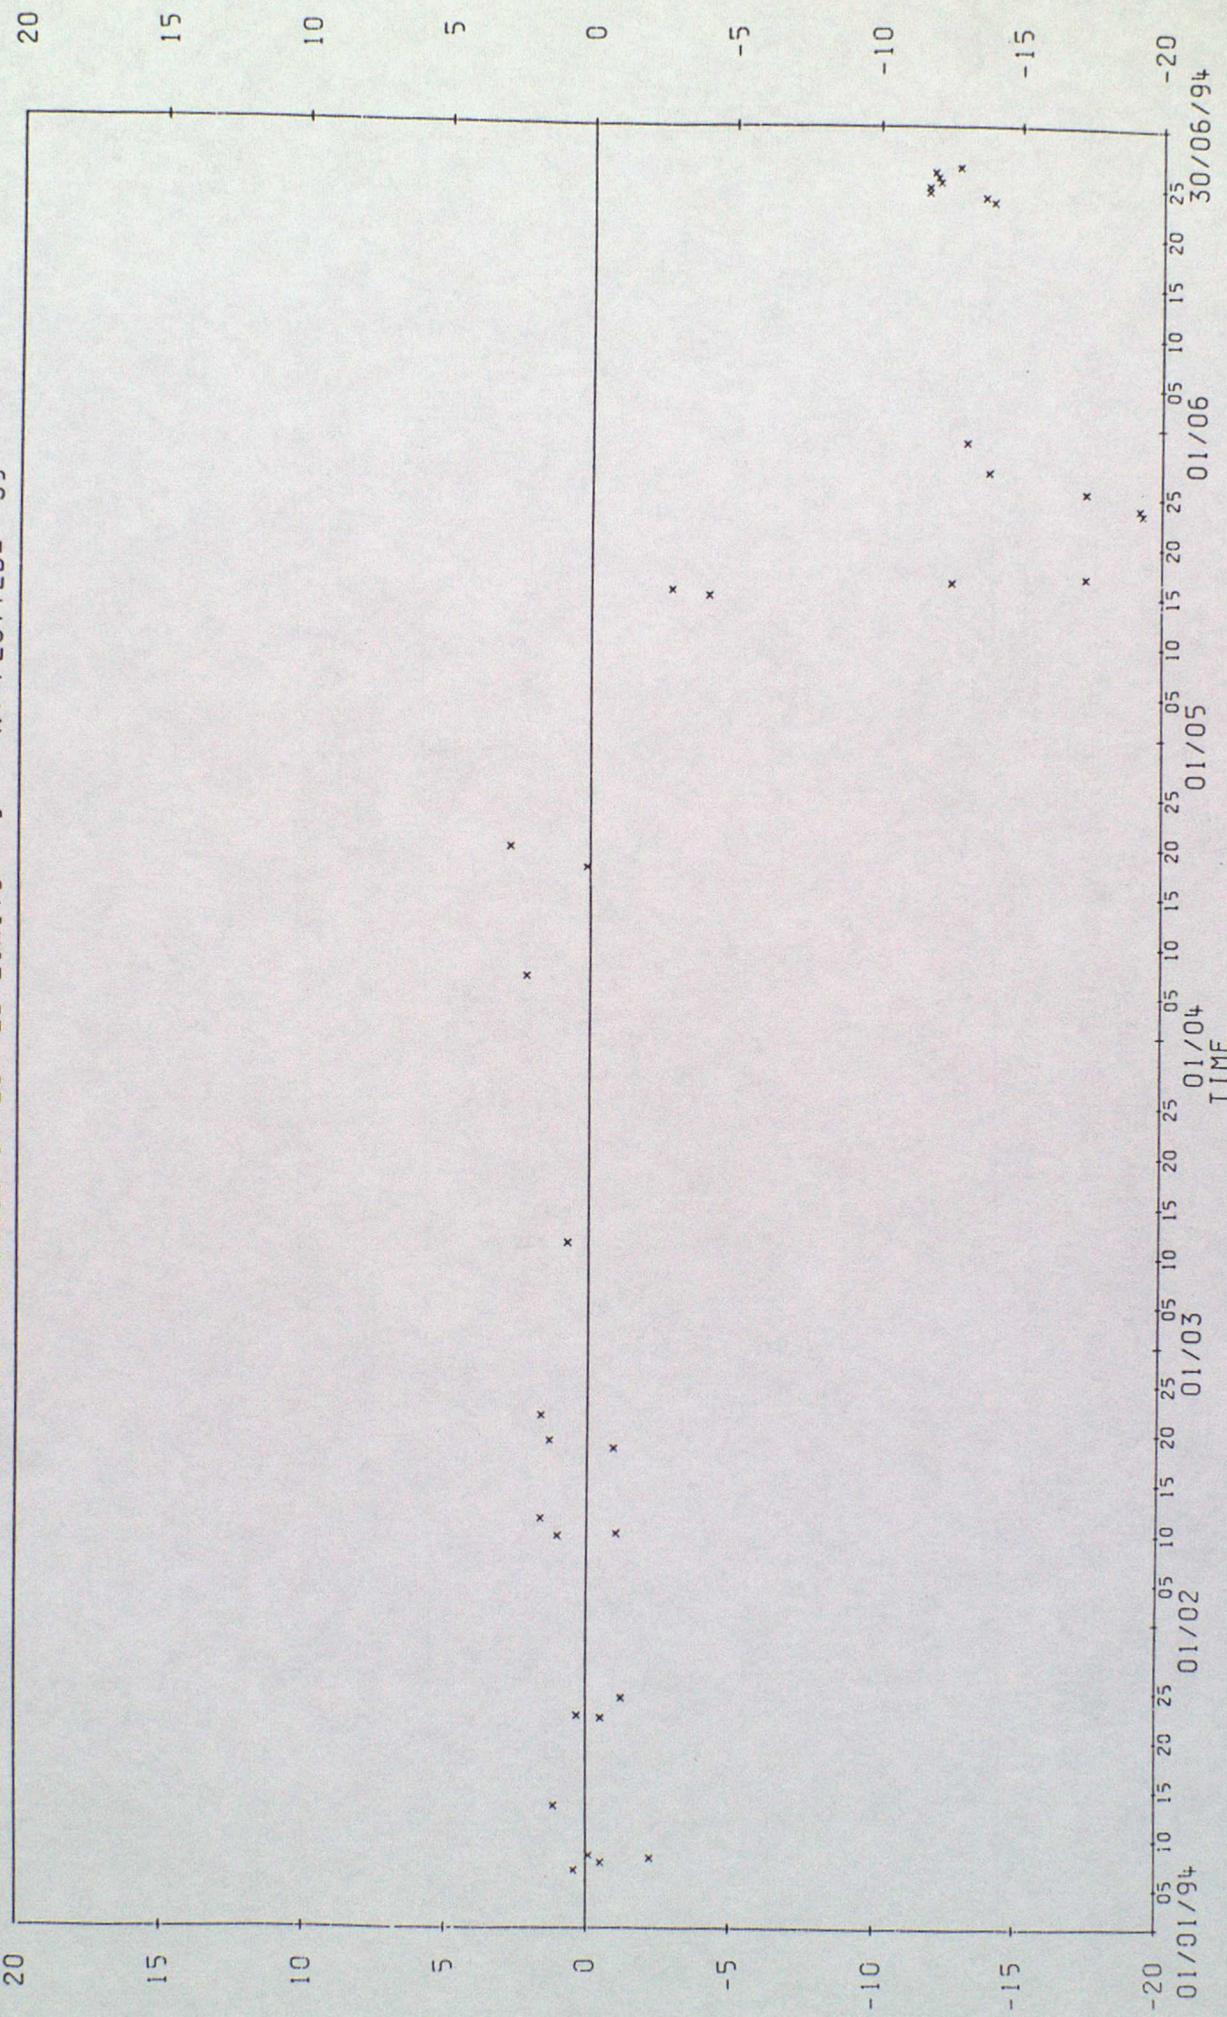

BRACKNELL MONITORING INFORMATION FOR MARINE SURFACE DATA
TIME SERIES OF OBSERVATION MINUS BACKGROUND INCREMENTS(0-B) FOR IDENTIFIER: UPIU
0-B

VARIABLE : MSLP IN UNITS OF HPA
