METEOROLOGICAL OFFICE

THE OBSERVATORIES' YEAR BOOK 1926

Comprising the meteorological and geophysical results obtained from autographic records and eye observations at the observatories at Lerwick, Aberdeen, Eskdalemuir, Cahirciveen (Valentia Observatory), and Richmond (Kew Observatory), and the results of soundings of the upper atmosphere by means of registering balloons.

Published by the authority of the
METEOROLOGICAL COMMITTEE

LONDON:
PUBLISHED BY HIS MAJESTY'S STATIONERY OFFICE
To be purchased directly from H.M. STATIONERY OFFICE at the following addresses:
Adastral House, Kingsway, London, W.C. 2; 120, George Street, Edinburgh;
York Street, Manchester; 1, St. Andrew's Crescent, Cardiff;
15, Donegall Square West, Belfast;
or through any Bookseller.

PREFACE.

Up to the end of 1921, the serial statistical publications of the Meteorological Office were grouped together as though they were parts of one comprehensive book. This book, which was entitled "The British Meteorological and Magnetic Year Book," consisted of :—

Part I	The Weekly Weather Report.
Part II	The Monthly Weather Report.
Part III, Section I	Daily Readings at Meteorological stations of the First and Second Orders.
Section II	Geophysical Journal, Daily Values of Meteorological and Geophysical Elements.
Part IV, Section I	Hourly Values from Autographic Records. Meteorological Section.
Section II	Hourly Values from Autographic Records. Geophysical Section.
Part V	Réseau Mondial.

The data for the year 1922 and subsequent years are found in the following publications :—

New Publication from 1922.	Corresponding parts of the British Meteorological and Magnetic Year Book until the end of 1921.
The Weekly Weather Report	Part I.
The Monthly Weather Report	Part II.
The Observatories' Year Book	Part III, Section II. Part IV, Section I.* Part IV, Section II.
The Réseau Mondial	Part V.

It will be noticed that Part III, Section I, of the old publication is not included in the new issues. This part contained "Daily Readings at Meteorological Stations of the First and Second Orders," and it has been decided that as the new Observatories' Year Book contains daily values of the meteorological elements for the principal first order stations and the Daily Weather Report contains daily values for these and about 40 other stations, it is not necessary to revive the issue of this section, which ceased with the data for 1921.

The present volume is the fifth issue of the Observatories' Year Book. It contains geophysical data for Lerwick, Eskdalemuir, Valentia and Kew, meteorological data for Aberdeen, Eskdalemuir, Valentia and Kew, and in addition an aerological section giving the results of soundings of the upper atmosphere by means of registering balloons.

The principal addition to this volume is a set of tables of hourly values of the magnetic elements as recorded at Lerwick Observatory.

The table of mean annual values of magnetic data for observatories of the globe has been contributed by the Astronomer-Royal. It will be found in the Eskdalemuir section.

---

* Part IV., Section I.—Hourly Values from Autographic Records, Meteorological Section, was discontinued after the data for 1913 had been published, and it is not proposed to continue it to the end of 1921 as is the case with the other sections.

(44.) Wt. 12,246—6,002/746. 275. 8/28. T.S. 66.

Note.—The height given is that of the site of the rain-gauge. The heights of other meteorological instruments are shown under the appropriate Tables.

NORMAL VALUES AND MONTHLY SUMMARIES.

Monthly and annual normals of pressure, dry bulb temperature, and rainfall for each hour of the day and for the period of 45 years, 1871–1915, are published for the observatories Aberdeen, Cahirciveen, Richmond and Falmouth in *Hourly Values from Autographic Records*, 1917 (Part IV. of the British Meteorological and Magnetic Year Book, 1917), and in previous volumes of that series. Corresponding normals of wind-speed and sunshine are published there for the same observatories and for the period of 35 years, 1881–1915 ; while corresponding normals of relative humidity are also published there for the period of 30 years, 1886–1915.

For Eskdalemuir the same publication gives hourly averages for the months and for the year, referred to the period 1911–1915.

Monthly Summaries giving additional mean values and frequencies of occurrence of various meteorological phenomena will be found for all the observatories in *The Monthly Weather Report* and its Annual Summary. The latter also contains special summaries of the tabulations of the anemographs.

GENERAL INTRODUCTION TO THE METEOROLOGICAL TABLES.

The elements dealt with in the following meteorological tables for the Observatories at Aberdeen, Eskdalemuir, Cahirciveen and Richmond are :—barometric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, minimum night temperature on the grass, cloud and weather, and in some cases temperature in the ground, solar radiation and level of underground water.

The positions of the Observatories and the heights of the sites are given on p. 8.

NOTES ON THE INSTRUMENTS AND TABULATION OF THE RECORDS.

A detailed description of the barograph, thermograph, and Beckley raingauge used for obtaining the records of pressure, temperature, humidity, and rainfall is given in the *Reports* of the Meteorological Office for the years 1867 and 1869 ; for a description of other instruments in use reference may be made to the *Meteorological Observer's Handbook* and to the article on Meteorological Instruments in the *Dictionary of Applied Physics*, Vol. III. The following notes are supplementary and are given partly for reference and partly as containing information necessary for the interpretation of the tables.

Barometer.—The record of barometric pressure is obtained photographically from a mercurial barometer.

A beam of light is passed through the space between the surface of the column of mercury and the top of the tube, and, after passing through a diaphragm which reduces the width of the beam of light to a very narrow sharp line, is focussed upon a sheet of sensitised paper (ordinary " bromide " paper is employed) carried upon a cylinder which is rotated by clockwork and makes one revolution about its vertical axis in rather more than 48 hours.

The *barogram* is therefore a continuous photograph of this narrow vertical line, and appears as a horizontal ribbon, the depth of which is constantly varying with the rise or fall of the mercury in the tube of the barometer.

The expansion of a zinc rod is utilised to compensate for the effect of temperature upon the height of the barometric column ; the arrangement produces mechanically a lengthening of the beam of light at its upper end as it becomes shortened at its lower extremity by the expansion of the mercury in the tube. A time-scale is recorded upon the barogram by means of a shutter actuated by the clock. This shutter cuts off the light for the space of four minutes every two hours, thus producing interruptions which appear as narrow white spaces on the record corresponding with known points of time. Until 1918 these time-breaks occurred at the even hours, 2h, 4h, 6h, etc., but it was found that when the edge of the record was not critically sharp owing to various causes, a systematic error was introduced when measuring the records, whereby the values at the even hours were slightly in excess of those at the odd hours where no time-break existed. From 1918 onwards the clock was so arranged that the time-breaks should occur half an hour before the even hours ; by this means both even and odd hour-values are measured at points on the trace which are unaffected by any systematic difference.

Control readings of a standard barometer are taken three times a day by different observers. The control readings are first corrected for index error, temperature and gravity, and then compared with the corresponding readings of the barogram. The differences between the control readings and the corresponding tabulated values are then found and a correction derived therefrom is applied to all the tabulated values. This correction, known as the "residual correction," is so applied as to run smoothly throughout the whole length of each record—a period of 48 hours—and alterations in the amount of the correction occur, where necessary, in steps not exceeding 0·1 millibar.*

The scale value of the barograms is found from a comparison of a series of such standard and curve readings. The indications of a curve are converted into numerical values by measuring the ordinates with a tabulating instrument, graduated according to the ascertained scale value.

Thermometers.—The air temperature data at each Observatory are derived from records obtained photographically from two mercurial thermometers. One thermometer is used as a dry bulb and the other as a wet bulb thermometer.

Each thermometer has a large cylindrical bulb four inches long and a very long stem. The latter is bent twice at right angles to enable the bulb to be exposed outside the building in a louvred screen attached to the north wall of the Observatory.† The column of mercury in the vertical portion of the stem inside the building is broken at a convenient point by a small air space which moves up or down the stem with rise or fall of temperature. The record is obtained by passing a reflected beam of light through the air space and photographing its image upon a moving sheet of "bromide" paper in the same manner as described in the case of the barometer. A base line is traced on the paper by a pencil of light passing through a small aperture in the brass frame carrying the recording thermometer. The time-scale is automatically recorded upon the curves, a time-break occurring half an hour before each even hour.

Two large standard thermometers with very open scales graduated in degrees absolute and having bulbs similar to those of the thermograph are mounted in the screen side by side and close to the thermograph bulbs. One of the thermometers is arranged as a dry bulb, the other as a wet bulb. Control readings of these thermometers are made three times a day for comparison with the corresponding readings obtained from the thermograms.

The scale-value of the curves is found by a comparison of the readings of the standard thermometers, corrected for any errors they may have, with the corresponding measurements of the curves. The curves are measured by means of a plate of glass ruled with lines corresponding with the ascertained scale-value of the record, both for degrees and for time. The scale is graduated so as to read degrees vertically and hours horizontally.

Two alternative methods of reading the curves have been adopted.

(*a*) At Kew and Valentia observatories the scale is set by the base-line and after hourly readings have been obtained for the whole record comparisons are made with the control readings. The residual correction so determined (normally the same for the whole record of 48 hours) is applied to the tabulations.

(*b*) At Aberdeen and Eskdalemuir observatories, the practice is to adjust the glass scale so that the readings at the control hours on the trace are made to show general agreement with the corresponding eye-readings of the standard thermometers. The temperature equivalent of any part of the curve can then be read off. The base-line photographed on the record serves as a useful check.

---

* At Valentia and Kew Observatories the rule is to apply the same correction for the whole chart.

† At Eskdalemuir the screen stands in the open.

Rainfall.—This element is recorded by a Beckley self-registering raingauge, in which the rain as it falls is collected in a receiver supported on a float in a vessel of mercury. As the rain passes into the receiver, the float gradually sinks, carrying with it a pen which records its position upon a paper stretched upon a clock-driven cylinder. The displacement of the mercury by the float is arranged so as to give a uniform scale throughout. When five millimetres (two-tenths of an inch) of rain have entered the receiver a siphon comes into action, and, by discharging its contents, causes the float to rise till the pen is brought back to the zero line, from which the record begins again.

The collecting funnel of the Beckley raingauge has an area of approximately 100 square inches. Each gauge stands on level ground and its distance from every other object is greater than twice the height of the object. The height of the rim of the Beckley raingauge above the surface of the surrounding ground varies from 0·4 m. to 0·6 m. at the different observatories. Details are given at the head of the tables of hourly values. A check gauge with funnel 8 inches in diameter is installed near by.

The records obtained from the Beckley self-registering raingauge are, if necessary, subjected to a proportional correction whereby they are brought into agreement with the amount of rainfall as recorded by the check raingauge read twice daily.

Sunshine.—The record of sunshine is obtained from a Campbell-Stokes recorder, in which instrument the sun's rays are focussed through a 4-inch spherical lens of crown glass upon a strip of blue card, which is scorched, or burned right through, according to the intensity of the sun's rays. Three different patterns of card are used at different seasons of the year. The cards are exposed in a metal bowl, and the focussed image of the sun leaves its mark behind it as it travels along the surface of the card with the apparent motion of the sun through the heavens. The intensity of the burn is not measured, but the record is regarded as that of " bright " sunshine whenever the card has been distinctly scorched. When measuring the duration of sunshine which is represented by intermittent burns, an allowance is made for the extension of the trace by the charring of the card.

Wind-Speed and Direction.—The hourly values of wind-speed and direction which appear in this volume are derived from the records of Dines tube anemographs. These instruments record the speed of the wind and its direction directly as functions of the time. For previous volumes the hourly values of wind-speed and direction were derived from the records of Robinson Cup Anemographs, except at Eskdalemuir, where the records of tube-anemographs have always been used for the purpose of hourly values. Particulars of the exposure of the tube-anemographs at the several observatories will be found in the introductions to the data for each observatory. A description of the tube-anemograph will be found in the *Meteorological Observer's Handbook.*

The exposures of the tube and cup anemographs at Richmond (Kew Observatory) are in some respects similar to one another, both instruments being mounted at the same level upon the observatory building. At Aberdeen and Cahirciveen (Valentia Observatory) the exposures of the two instruments are, however, quite dissimilar. At these observatories the tube anemographs are erected at the top of masts, away from buildings, while the cup anemographs are mounted on the observatory buildings. As a result of these differences in exposure, there is at each observatory a fairly systematic difference between the records of speed from the two instruments, the difference being mainly a function of the wind-direction. In order to obtain a measure of the difference, the hourly tabulations for a period of about two years have been grouped according to wind direction, and the average value of the quantity

$$100 \times \frac{\text{Speed by tube anemograph}}{\text{Speed by cup anemograph}}$$

has been determined for each direction and for each observatory, with the following result :—

Average values of the quantity $100 \times \frac{\textit{Speed by tube anemograph}}{\textit{Speed by cup anemograph}}$
at the three observatories arranged according to the direction of the wind.

North = 360°, East = 90°, South = 180°, West = 270°.

180	135	134	95	360	135	102	104

These values are shown graphically in the diagram on page 13.

Minimum Night Temperature on the Grass.—This is the temperature determined by a minimum thermometer exposed freely over the surface of the grass. The thermometer is enclosed in an outer glass jacket which surrounds its stem, but leaves the spirit bulb freely exposed to the air. The thermometer is supported on two small Y-shaped pieces of wood so that it lies horizontally, with its bulb about one or two inches above the ground which is covered with short grass. When snow has fallen the thermometer is supported so as to lie just above the surface of the fallen snow, but not touching it.

The thermometer is laid out at 18h. each day, having been kept in an upright position, bulb downwards, inside the Stevenson Screen during the daytime, so that any spirit that may have condensed in the upper part of the stem may be able to run down and join the main spirit column.

Notes on the Tables.

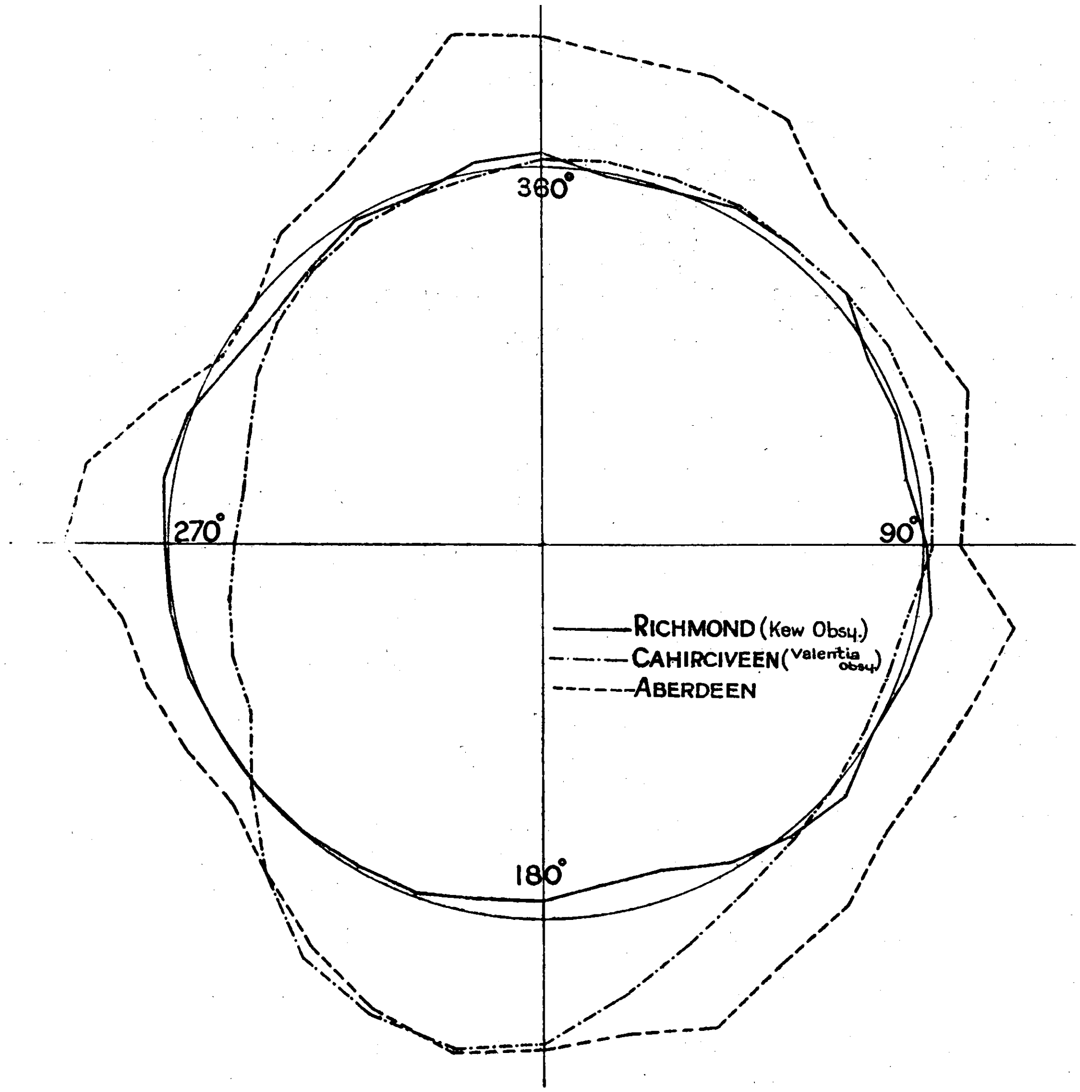
General.—Interpolated values are printed within brackets, ( ). Maximum and minimum values are printed in heavy type.

Standard of Time.—The observations are referred to *Greenwich Mean Time* except as regards sunshine, for which element *local apparent time* is used.

Units.—In accordance with the practice introduced in 1911, as a consequence of certain resolutions of the Gassiot Committee of the Royal Society, the values in the tables are expressed throughout in units based upon the C.G.S. System : tables for conversion to other units are given in the *British Meteorological and Magnetic Year Book* (*Part IV*) for 1913 and are also to be found in the *Computer's Handbook.*

Daily Mean Values.—The daily means of pressure, temperature, relative humidity and wind speed are obtained by adding half the sum of the values for the initial and final midnights to the sum of the 23 intermediate hourly values and dividing by 24.

In the preparation of the tables of diurnal inequalities for individual months and for the year, it is assumed that the difference of value between the means for the initial and final midnights, which may be termed, so far as the hourly variations are



COMPARISON OF WIND SPEEDS FROM DIFFERENT DIRECTIONS AS RECORDED BY THE TUBE AND CUP ANEMOGRAPHS AT ABERDEEN, CAHIRCIVEEN AND RICHMOND.

The directions from which the wind blows are indicated by the four cardinal points of the compass, a north wind being marked 360°, an east wind 90°, a south wind 180° and a west wind 270°. The radius of the circle which is drawn in a continuous thin line represents 100 per cent. and indicates equality between records of speed from the two kinds of anemographs. The irregular curves are so drawn that the lengths of the radii vectores to the middle point of the diagram are, for the different wind directions, represented by the percentage numbers set out in the table on the preceding page.

concerned, the non-cyclic variaticn, is equally distributed over the whole 24-hour period. Thus, in a table of diurnal inequalities the entry d_n for the hour n is given by

$$d_n = x_n - \bar{x} - (n - 12)\ (x_{24} - x_0)/24,$$

x_n being the value of the element at hour n and $\bar{x}$ the mean for 24 hours.

Annual Values.—The mean values or totals for the whole year (given either in separate tables or at the end of the corresponding monthly tables), are computed as the means or sums of 365, in leap year 366, daily values.* The annual mean values of pressure at sea level are computed from the annual means at station level and the annual means of air temperature ; the annual means of vapour pressure are derived from the annual means of air temperature and relative humidity.

Atmospheric Pressure.—All pressures recorded in this volume are expressed in *millibars*, one millibar being equal to 1000 dynes per square centimetre. The following are the values of physical constants used in evaluating the data :—

Density of Mercury = 13·5955 grams per cc. at 0°C.

Intensity of Gravity at Sea Level (Lat. 45°) = 980·617 centimetres per second per second.

1 inch = 25·4000 millimetres.

* At Eskdalemuir the annual values for the years 1922 to 1926 were computed as the means or sums of 12 monthly values.

Hence 1000 millibars corresponds with a reading of 750·076 millimetres, on a mercury barometer at temperature 0°C. in Lat. 45°, or 29·5306 inches under standard conditions of temperature (mercury at freezing point, scale at 62° F.) in Lat. 45°.

As a millibar is a pressure, it can only be obtained from the reading of a barometer after the latter has been suitably corrected for

(*a*) index error,
(*b*) temperature,
(*c*) gravity.

All these corrections have therefore been applied to the barometer readings in obtaining the pressure values published in this volume. The corrections for temperature and gravity have been obtained from tables consistent with the *International Meteorological Tables*. (Gauthier-Villars, Paris, 1890.)

Unless otherwise stated all pressure values refer to the level of the observatory as given in the headings of the tables. The reduction to Mean Sea Level, if made, has been calculated from tables prepared for each observatory from the formulæ of the *International Meteorological Tables.*

The tables contain values of pressure at exact hours obtained from the photographic barograms in the manner described on p. 9; also daily, monthly and annual means of hourly values, together with the monthly and annual means of diurnal inequalities. Monthly and annual means of the hourly values after reduction to mean sea level are also given.

There is also a table showing the daily extremes of pressure, *i.e.*, the maximum and minimum values recorded during each day.

Temperature.—The scale on which temperatures are recorded is such that the freezing point of water under atmospheric pressure is 273 a. precisely. Other temperatures differ by 273·0 from readings on the Centigrade scale.

The scale approximates to the absolute scale defined by Lord Kelvin, on which the temperature of the freezing point is 273·1 to the nearest tenth of a degree.* Accordingly, to convert temperatures published in this volume to the Kelvin scale, a correction + 0·1 is to be added to each reading.

As an alternative to the application of this correction modified values may be used for the constants which enter certain formulæ. For example:—At temperature t on the scale adopted in the Year Book, the radiation according to Stefan's Law† is

$$5{\cdot}709\times10^{-5}\,(t+0{\cdot}1)^4\ \text{erg/(cm.}^2\text{ sec.)};\quad \text{or } 5{\cdot}717\times10^{-5}\,t^4\ \text{erg/(cm.}^2\text{ sec.)}$$

In using the modified formulæ we are virtually adopting a scale of temperature with the degrees greater than those of the Centigrade scale, in the ratio of 273·1 to 273. This is the practice of the *Computer's Handbook* of the Meteorological Office.

The tables give the values of temperature at exact hours obtained from the photographic thermograms; also daily, monthly and annual means of hourly values, together with the monthly and annual means of diurnal inequalities. There is also a table showing the daily extremes of temperature.

Humidity.—When the temperature of the wet bulb is above 273a, values of relative humidity at exact hours are deduced from the corresponding values of dry and wet bulb temperatures obtained from tabulations of the photographic thermographs, complete saturation being taken as 100. Until the end of the year 1925 the reduction was effected from tables based on Glaisher's hygrometric factors‡ but from 1st January, 1926, tables have been employed which proceed from Regnault's formula

$$x = f - Ap\,(t - t^1)$$

where x = vapour pressure under the conditions of observation.
f = saturation vapour pressure at the temperature (t^1) of the wet bulb.
p = pressure of the air.
t = temperature of the dry bulb in absolute (Centigrade) degrees.
t^1 = temperature of the wet bulb in the same units.
A = a "constant."

* A. L. Day and R. B. Sosman, *Dictionary of Applied Physics.* Macmillan, London, 1922. Vol. I., p. 840.

† The constant 5·709 is the value which has been adopted by the International Research Council for publication in the "*International Critical Tables.*"

‡ Glaisher's Hygrometrical Tables, 7th edition, London.

The tables used in this volume for determining the hourly values of relative humidity when the wet bulb is above the freezing point are *Jelineks Psychrometer-Tafeln* (6th edition, Leipzig, 1911). They give values which are in almost exact agreement with those given by *Hygrometric Tables* published by the Meteorological Office in 1924 (M.O. 265) for general use at second and third order stations. The latter tables are not suited to the purposes of this Year Book, because in them temperature is expressed in Fahrenheit degrees, whereas the absolute centigrade scale of temperature is used at the observatories.

No allowance for variation of pressure p is made and the standard value used in Jelineks tables, *i.e.*, 755 mm. of mercury (1006·57 mb.) is adhered to. Similarly no allowance is made in the adopted value of the constant " A " for the speed of the air flowing past the wet bulb, though it is well known that " A " is not independent of the ventilation. " A " is regarded as fixed and equal to ·0008.

In view of the well-marked diurnal variation of wind-speed, the diurnal variation of humidity, derived in this manner, is subject to slight modification.

When the wet bulb reading does not exceed 273a, the above method of reduction is not followed, but values of relative humidity are derived from the record of the hair hygrograph. To these values are applied appropriate corrections based on a comparison between the readings of the record of that instrument and the corresponding values of humidity computed from dry and wet bulb readings during neighbouring periods when the wet bulb readings exceeded 273a.

The mean hourly values of vapour pressure are computed by slide rule from a table* of saturation vapour pressure over water and the corresponding mean hourly values of relative humidity and air temperature.

The normal hourly values of relative humidity for the period 1886–1915, published for certain Observatories in " Hourly Values from Autographic Records, 1917," were derived from tables based on Glaisher's factors. The application of the new tables to the normal hourly values of dry and wet-bulb temperature gives results for normal relative humidity which are only slightly different from those which have been published. At Kew Observatory in winter the difference is negligible; in July it does not exceed 1 per cent. at any hour, in October it does not exceed 2 per cent. at any hour. The effect is greatest in April when the published normal values of average relative humidity are reduced by 3 per cent. at noon and at 16h. and by smaller amounts at other hours.

Of greater importance is the effect on the values of absolute minimum humidity. Under the old system, values of relative humidity less than 30 per cent. seldom occurred; under the new system, values less than 20 per cent. may occur not infrequently. The following examples illustrate the extent to which published values may be affected by the use of the new tables in place of Glaisher's tables.

RICHMOND (KEW OBSERVATORY).

Occasions on which relative humidity would be considerably affected by the change in humidity tables.

Date and Hour.	Dry Bulb. °F.	Wet Bulb. °F.	Relative Humidity.	
			Glaisher's Tables (published value).	New Tables.
April 9, 1909.			%	%
12h	61·9	46·1	32	19
13h	64·1	47·0	31	17
April 23, 1912.				
15h	63·0	46·1	31	16

* The saturation vapour pressures used are those employed in the preparation of *Hygrometic Tables.* They are equivalent to those published by Scheel and Heuse in *Annalen der Physik,* 1910.

Tables are printed giving the values of relative humidity at exact hours together with daily, monthly and annual means of hourly values. Monthly and annual means of vapour pressure computed from the corresponding mean values of temperature and relative humidity, together with monthly and annual means of diurnal inequalities of relative humidity, are also given.

Rainfall.—Tables are given showing for the 60 minute intervals between exact hours* the amount of precipitation, expressed in millimetres, derived from the record of the Beckley gauge (see p. 11). Totals of amount are given for each day, and for each month; the latter totals referring both to the complete days of the month, and to each of the hours of the day. When zero rainfall is assigned to a particular hour, the entry appears as " ... ". Corresponding totals of duration of rainfall are also given, the duration being regarded as the number of hours during which rain falls at a rate of not less than 0·1 millimetre per hour. If slight precipitation, due to rain, snow, fog or dew, extends over some hours, and if the amounts collected in some or all of the hours are less than ·1 mm., the fact is indicated by a succession of entries, each of which is enclosed within brackets, covering the period over which precipitation is known or believed to have occurred. In such cases entries of (·1) are allocated evenly among the hours concerned in such a way that their sum is equal to the aggregate fall during the period, and the remaining entries are (...), (*), (≡:) or (⌓) according as the precipitation took the form of rain, snow, fog or dew. Slight precipitation which takes other forms such as hail, sleet, hoar frost, glazed frost and rime is dealt with similarly. When it is impossible to determine the hourly amounts of precipitation, *e.g.*, during snowfall or on occasions when the record has failed, the normal procedure is to consider each case on its merits, and to assign hourly values derived from estimates made by the observers as soon as possible after the event. Such values are also enclosed in brackets.

Annual totals of hourly amounts and duration and notes on special features of the rainfall of the year are also given.

Sunshine.—Tables are given showing for each of the 60-minute intervals between exact hours† according to *local apparent time*, from sunrise to sunset, the duration of bright sunshine recorded by the Campbell-Stokes instrument. The sums and means of hourly amounts are also given. For each day is shown the total duration of bright sunshine, and also the percentage this represents of the " possible " duration for the day. The " possible " for each day is computed as the period of time beginning and ending at the instants when the centre of the sun is apparently on the horizon, due allowance being made for atmospheric refraction. Even on a clear day the sun, when at an altitude less than $2\frac{1}{2}°$ to $3°$ above the horizon, fails to make a scorch on the card of the Campbell-Stokes recorder.

A distinction is made in the tables between (*a*) sunshine not possible, and (*b*) sunshine possible but none recorded. If, in any hour, sunshine is not possible, the symbol " — " is used; if more than 3 minutes of " possible " sunshine falls in the 60-minute interval between exact hours according to local apparent time, and if no sunshine was recorded the symbol " ... " is printed.

The values for the months and for the year of percentage of possible duration of sunshine are obtained by comparing the total recorded sunshine for the period with the total " possible " sunshine for the period.

---

* For the years 1904 to 1920 it was the practice to tabulate rainfall for the period of 60 minutes centred at the exact hours; the reversion to the method in use for 1903 *et ante* occurred on 1st January, 1921.

† Previous to 1st January, 1921, sunshine was tabulated for the period of 60 minutes centred at exact hours.

Wind.—Tables are printed giving the hourly values of wind speed and direction, together with the mean speed for each day, each hour, and for the month and year. Values of speed are expressed in metres per second (1 metre per second = 2·2369 miles per hour) : those of direction are given in degrees from true north. The values of direction* and speed are averages for periods of sixty minutes, centred at the exact hours of Greenwich Mean Time. They are obtained by estimation from the records with the aid of a glass scale, the transparent part of which has a width corresponding with one hour on the time scale of the record.

For speeds not exceeding 1·5 m/s the wind directions are regarded as indeterminate and are omitted.

The daily values of the speed and time of occurrence of the maximum gust and the monthly distribution of wind are shown in other tables.

Minimum Night Temperature on the Grass.—Values are given for each day of the year together with monthly and annual mean values. The interval to which the reading refers is from 18h the previous day to 7h on the day to which it is entered.

Diary of Cloud and Weather.—In these tables are given particulars of the cloud forms observed daily at 7h, 13h, and 18h, the total cloud amount observed at 7h, 9h, 13h, 15h, 18h, and 21h, the range of visibility at each of these six hours and the kind of precipitation which may be falling at those hours. There is also a column devoted to remarks on the weather of the day.

Cloud Form.—The observations of cloud form are made in accordance with the International classification, and the following abbreviations are used in the tables :—

Cirrus	Ci.
Cirro-Stratus	Ci-St.
Cirro-Cumulus	Ci-Cu.
Alto-Cumulus	A-Cu.
Alto-Stratus	A-St.
Strato-Cumulus	St-Cu.
Nimbus	Nb.
Cumulus	Cu.
Cumulo-Nimbus	Cu-Nb.
Stratus	St.
Stratus-cumuliformis	St-Cuf.
Fracto-(prefix, as in fracto-stratus)	Fr-.
-lenticularis (affix, as in stratus-lenticularis)	-lent.
Mammato-cumulus	M-Cu.

All the cloud forms noted by the observer at the time of observation are printed where space permits. When the number of forms is too great to allow of this, the predominating forms selected at the time of observation to give the best representation of the cloud canopy are printed. If high or medium cloud can be seen, one of the selected types is normally a high or medium cloud.

Cloud Amount.—The figure given for the amount of cloud denotes the proportion of the sky covered by cloud, the numerical scale running from 0, cloudless, to 10, completely overcast. The figure denotes the total cloudiness irrespective of form. In the case of fog through which it is impossible to discern the sun or stars the cloud amount is entered as 10, but if cloud can be seen through the fog, the form and amount of that cloud are entered in the usual way. If the sun or stars are visible through fog and if there is no evidence of cloud above the fog the amount is entered as 0.

---

* Formerly it was the practice to take the direction at the exact hour. The present rule was adopted as from 1st May, 1915 (see also Introduction to *Hourly Values from Autographic Records*, 1913, p. xv.).

Visibility.—Observations of the range of horizontal visibility made every day at 7h, 9h, 13h, 15h, 18h, and 21h are printed in the diaries of cloud and weather this year for the first time.

As described in detail in the *Meteorological Observer's Handbook* (Ed. 1926), a series of selected objects, A, B, C . . ., as nearly as possible at the standard distances given in the table which follows, are used for this observation. The objects are selected so as to be readily seen and identified from specified observing points in daylight, when the air is clear. A variation up to 10 per cent. from the standard distances is considered admissible. Particulars of the objects in use at each observatory, together with a statement of their actual distances and bearings from the point of observation and notes on local peculiarities which affect the observations will be found in the Introductions to the sections for the individual observatories.

SCHEME FOR OBSERVATIONS OF RANGE OF VISIBILITY AND OF FOG, MIST AND HAZE.

Indication Letter of Object.	Standard Distance of Object.	Verbal Description.	Beaufort Letters.	
			Detailed Scale.	Contracted Scale.
	Metres.			
(X)	—	Dense fog	8 f	F.
A	25		7 f	
B	50	Thick fog	6 f	
C	100		5 f	
D	200	Fog	4 f	f.
E	500	Moderate fog	3 f	
F	1,000	Mist, haze or very poor visibility	m or z	m or z.
G	2,000	Poor visibility	m_o or z_o	m_o or z_o
H	4,000	Moderate visibility		
I	7,000			
J	10,000	Good visibility		
K	20,000	Very good visibility		
L	30,000			
M	50,000	Excellent visibility		

NOTE.—The grouping of the letters by the horizontal lines indicates the limits of the several figures of the International Telegraphic Code for visibility, from 0 to 9. The same grouping is also adopted in the tables of frequencies published in the *Monthly Weather Report*.

The method of observing consists in determining which is the most distant of the selected objects that can be identified and entering the corresponding letter. In cases of uncertainty when the observer, though recognising the presence of an object, would be unable to identify its nature from the observations he is able to make *at the time*, the letter corresponding with the next nearer object is entered. If object A, the nearest of the selected objects cannot be identified, an entry X is made. At night the letters are used to denote as nearly as possible corresponding degrees of atmospheric obscurity.

Small letters are used to indicate interpolations or extrapolations made in cases where it has not been possible to find suitable objects within 10 per cent. of the standard distances. In such cases the observer may use objects at other than the standard distances to guide his judgment. Particulars of such auxiliary objects will be found in the sectional introductions.

Fog, Mist and Haze.—The table of standard distances of visibility objects also summarises the descriptions used in connection with the phenomena of fog, mist and haze, and relates them to the scale of visibility. It also contains the Beaufort letters used for these phenomena in the Remarks column of the diary. In this Year Book as in other publications of the Meteorological Office, statistics of fog, mist and haze are based solely on visibility observations. The term *fog* is restricted to occasions when the visibility is less than 1 kilometre (*i.e.*, object F not visible); the terms *mist* and *haze* to occasions when the visibility is greater than 1 kilometre, but less than 2 kilometres (*i.e.*, object "F" visible, but "G" not visible). The distinction between mist (m) and haze (z) is determined by the depression of the wet bulb. When the visibility is between the limits specified for mist or haze, haze is recorded when the depression of the wet bulb is more than 1° F.; if the depression of the wet bulb does not exceed this limit, the term *mist* is used.

In previous volumes, occasions of haze, mist and fog were indicated by the International symbols for these phenomena, viz., ∞, ≡° and ≡ respectively, but the relation of these terms to the visibility scale was less rigorous. In order to indicate that a change in procedure has occurred in this matter, the three International symbols for haze, mist and fog have not been used in the tables in this volume.

Precipitation.—Whenever precipitation is falling at one of the six hours of observation there is printed in the Diary of Cloud and Weather under the heading "Precipitation" the International weather symbol which indicates the kind of precipitation, in accordance with the list below.

Remarks.—For the purposes of the column headed "Remarks on the Weather of the Day," it is usual to consider the day as divided into three portions, viz., morning, afternoon and night, denoted by *a*, *p*, *n*, respectively, but it should be noted that no arrangements are made for regular eye observation of weather changes in the period 21h 30m to 6h 30m.

The entries in the remarks column consist very largely of International weather symbols and the letters of the Beaufort scale. These symbols and letters are as follow:—

Beaufort Notation and International Weather Symbols.

b		blue sky, whether with clear or hazy atmosphere.
c		cloudy, *i.e.*, detached opening clouds.
o		overcast, *i.e.*, the whole sky covered with one impervious cloud.
g		gloomy.
u		ugly, threatening.
v	()	visibility, unusually clear atmosphere.
z		haze.*
m		mist, light fog.*
f		fog.*
fe		wet fog, *i.e.*, fog which deposits water copiously on exposed surfaces.
w		dew.
x	⊔	hoar frost.
	V	rime.
	~	glazed frost.
e		water deposited copiously on exposed surfaces, without rain falling.
y		dry air. (Relative humidity less than 60 per cent.)
p		passing showers.
d		drizzling rain.

r	●	rain.
	←	ice crystals in the air.
s	✱	snow.
rs		sleet.
		drift snow.
	⊞	snow lying. (More than half the surrounding country covered with snow.)
h	▲	hail.
	△	soft hail.
t	T	thunder.
l		lightning.
tlr		thunderstorm.
		gale.
q		squalls.
		solar corona.
	⊕	solar halo.
		lunar corona.
		lunar halo.
	⌒	rainbow.
		aurora.
		zodiacal light.
		mirage.

* To indicate varying intensities of haze, mist and fog the notation shown in the last two columns of the table on p. 18 is used.

The letter *i* preceding a letter or symbol which denotes some form of precipitation indicates that the precipitation is of an "intermittent" or "occasional" character.

The letter *j* preceding a letter or symbol which denotes some form of precipitation indicates that the precipitation is within sight, though not actually falling at the station.

The figure 0 written after and above a symbol indicates slight, whilst the figure 2 indicates strong or heavy; thus $\bullet^0$ slight rain, $\bullet^2$ heavy rain. The figures 0 and 2 written after and below the letters of the Beaufort notation are also used with a similar significance, thus d_0 slight drizzle.

The letters b, c, o, g and u, are used to describe the general appearance of the sky. The use of the letters g and u is sufficiently clear from the definitions given above. o is used whenever the sky is completely overcast with a uniform layer of thick or heavy cloud; c is used to denote that there is some cloud present, but o is not appropriate; b denotes that there is some blue sky.*

In order to meet difficulties which occur when there are only small quantities of cloud or blue sky present, c is not used unless the sky is more than a quarter covered, and b unless there is more than a quarter of the sky free from cloud. If there is more than a quarter of the sky covered with cloud and more than a quarter of the sky free from cloud b and c are both recorded.

The gale symbol is normally used in this publication to indicate that the wind as recorded by the anemograph averaged at least 17·2 *m/s* for one or more "centred" hours. At Richmond (Kew Observatory) the symbol has been used with the word gust in brackets to indicate the occurrence of gusts reaching 17·2 *m/s*.

---

* The present usage with regard to b, c and o dates from 1st Jan., 1926.

INTRODUCTION.

GENERAL REMARKS.

In 1919 the establishment of an observatory in the Shetlands was included in the programme of the Meteorological Office. A wireless station, built in 1913 by the Admiralty and transferred after the war to the Post Office, but used by that Department only in case of emergency, offered suitable accommodation in the way of offices and living quarters. It proved possible to make an arrangement under which the Air Ministry, on condition of maintenance of wireless plant, has the use of the station as an observatory and of the wireless plant for the reception of meteorological reports and time signals.

The Observatory was opened on the 7th June, 1921, when the first instalment of the instrumental equipment arrived. Later on in the same year the construction of a magnetograph house and of huts for absolute magnetic and auroral observations was commenced. The magnetograph house is a heavy concrete structure with walls 2 feet 6 inches (76 cm.) thick, of internal dimensions 16 feet by 10 feet (4·9 m. × 3 m.), and after construction several months had to elapse before the thick concrete walls and roof could be thoroughly dried and the recording instruments placed in position. These instruments, which are described below, consist of magnetographs recording magnetic declination and horizontal and vertical force. In addition, in order to obtain a record of the more minute changes in the vertical component of terrestrial magnetic force, a line of twin cable was laid in an approximately horizontal plane round Loch Trebister, the terminals of the cable being connected to a suitable galvanometer on which could be measured the current induced in the cable by changes in the vertical component of terrestrial magnetic force. The arrangement is similar to one in use at Eskdalemuir Observatory, but no records from either have yet been included in official publications.

Other instruments installed at the Observatory included barometers, barograph, hygrograph, psychrometers, nephoscope, raingauges (ordinary and self-recording), sunshine recorder and Dines tube anemograph. But meteorological observations have been restricted, and the time of the somewhat limited staff available has been devoted chiefly to magnetic work.

The present is the fourth complete year of magnetic observations. Instrumental difficulties still occur, but it has now been decided that publication of hourly values of Declination, Horizontal and Vertical Force, in addition to the summaries formerly included, is justifiable and desirable.

The site and the work in Terrestrial Magnetism will now be described.

SITE.

The Observatory is situated on a ridge of high ground about a mile and a half (2·4 km.) to the south-west of Lerwick and adjoins the main road between Lerwick and Scalloway. The site slopes upward from west-north-west to east-south-east, the average height above M.S.L. being about 280 feet (85 metres). The ground to the east and south-east rises slightly for about ¼ mile (·4 km.) then slopes sharply down to the sea. In other directions there is a downward slope for about ¼ mile extending to the Loch of Trebister on the south-west, Sandy Loch to north-west, and to the Burn of Sound to north-north-west; beyond these and distant about ¾ mile (1·2 km.) from the Observatory are small hills—Munger Hill to the south is about 320 feet (97 metres) above M.S.L., Shurton Hill to west-north-west rises to 576 feet (176 metres), and Stony Hill to the north to about 400 feet (122 metres). In clear weather it is possible to see the Outer Skerries, 25½ miles (41 km.) north-east by north, and Sumburgh Head, 20 miles (32 km.) south by west; the horizon in other directions is limited to a few miles.

The average depth of soil in the vicinity is about a foot, and outcrops of sandstone occur in many places. The surrounding country is barren and desolate, the only vegetation being coarse grass, stunted heather, and moss, with occasional patches of bare black peat. The Observatory ground is of a very uneven nature, and, owing to lack of proper drainage, is frequently water-logged; in winter it may be almost submerged for considerable periods. Views of the station are shown and the arrangement of buildings and situation of instruments are set out on a site plan in the 1923 Year Book.

ATMOSPHERIC ELECTRICITY.

Notes on the Instruments.—A Benndorf electrograph was in operation, with somewhat frequent interruptions to the record, until 24th July, when it was sent away for overhaul. From 6th to 24th July, and after it was returned late in December, the instrument was housed in a more accessible position in the N.W. corner room of the office block; a full description of this site will appear in the Year Book for 1927. The observations now published are nearly all from the old site, where the instrument was installed in a small wooden hut, size 1·5 × 2·0 metres, height 1·7 m. to eaves, 2·5 m. to ridge, situated within the grounds of the Observatory; an oil stove was kept burning in the hut to maintain the insulation. The collector rod passes through the N.E. corner of the hut. The collector, which projected 89 cm. from the wall of the hut, consists of a copper spiral about 5 cm. long, painted over, by means of a special adhesive varnish, with a salt of radium. This is soldered into the smaller end of a tapered German silver tube, 76 cm. long, and of triangular cross section, which in turn is attached to a "Duralumin" tube, 89 cm. long and 1·3 cm. in diameter. The latter tube passes through a hole, 3·8 cm. diameter, in one end of a wooden box (dimensions 38 × 25 × 10 cm.), where it is supported horizontally between the ends of two metal rods embedded in sulphur. A number of small 2 volt electric bulbs are kept burning inside the box in order to improve the insulation of the supports for the collector rod during wet weather, and a similar bulb is placed inside the case of the electrometer. The rod is connected to the base of the acid pot of the Benndorf electrometer by a fine wire. A detailed description of this instrument is to be found in *Phys. Zeit.* 7 (1906), p. 98, whilst the general principle is described in Mathias' *Traité d'Electricité Atmosphérique et Tellurique*, p. 54, and in Chauveau's *Electricité Atmosphérique*, pp. 61–64.

The record consists of a series of dots made once a minute on a long roll of paper as it is unwound from a drum by clockwork. The time scale is approximately 4 cm. to the hour, but varies considerably; this variation is not of much importance as hour marks are made automatically and as each individual minute is marked by a dot on the trace. A zero line is obtained by connecting up marks made by earthing the needle of the electrometer. At first these zero marks were made only at the beginning and end of each day, but an intermediate zero mark is now made. Owing to the constancy of the perpendicular distance between the zero line and the line through the hour marks, further intermediate positions of the zero are easily obtained. It has been found that on days which must be regarded as normal, some trace has been lost and, from 1st May, the sensitivity of the record was decreased considerably.

The insulation of the system is tested frequently, the procedure being to remove the collector and to charge the needle. The rate of leak is obtained for a period of 5 to 10 minutes. Considering the climatic difficulties the behaviour of the instrument in the matter of insulation has been very satisfactory. The rate of leak has been in general small, usually such that the instrument would lose half its potential in 15 to 20 minutes. Also, when the insulation breaks down it does it so thoroughly that the fact can easily be recognised on the traces and the spurious readings rejected.

Weekly scale tests are carried out with the aid of Ayrton-Mather Electrostatic Voltmeter No. 11889, and an auxiliary dry battery of approximately 300 volts. With the collector removed and one pole of the battery earthed, the electrometer is given succesive charges from the battery, commencing at about 90 volts, and rising by steps of 30 volts to 300 volts ; a dot is recorded on the sheet for each potential, which is also measured on the electrostatic voltmeter. On reaching the full voltage of the battery the measurements are repeated for decreasing potentials. It has been found that, for all practical purposes, the scale value may be taken as constant across the full width of the sheet, consequently a mean is taken of the values corresponding with each dot.

The scale values employed throughout the whole period were :—

January to April	13·1 v/mm.
May	27·2 v/mm.
June	24·9 v/mm.
1st to 5th July	23·6 v/mm.
6th to 24th July	14·85 v/mm.

The factor by which the recorded potential must be multiplied for conversion into potential gradient in the open is obtained from absolute measurements above a levelled piece of ground in the vicinity of the electograph hut. Observations are made of the potential attained by a wire stretched horizontally, and carrying a burning fuse exactly one metre above the ground at its centre. The factors (=0·78 for old site and 1·53 for new site) employed in reducing the values have been obtained from measurements made with either an Elster and Geitel leaf electroscope or Wulf electrometer No. 5225. No known change occurred in the position of the collector or in the surroundings, from the installation of the electrograph until the exposure factor was determined.

In its response to changes of potential gradient the instrument is very sluggish, compared for instance with the Kelvin water dropper in use at Eskdalemuir Observatory. In general the rise to a steady potential takes an approximately exponential character, and it was found that the mean of 34 tests gave 63 seconds as the time to rise to half the final value ; this is about 10 times as slow as the water dropper at Eskdalemuir Observatory. Sometimes when there is no wind the rate of rise of potential is very much slower and apparently nearly linear. If the instrument rises through a potential V and has a capacity C a quantity of electricity CV has to be given to the air in the neighbourhood of the collector, and in the absence of wind and the presence of fog this may hang about in the form of a heavily charged cloud for a considerable time before being dispersed. It is difficult to accept the readings from a radio-active collector during such times. Fortunately these conditions are rare at Lerwick except in early summer, but on the other hand they are then very interesting.

If we assume the leaking and the charging to be exponential, i.e.—

$$\text{If } \frac{dV}{dt} = -K_L V$$

$$\text{and } \frac{d(V_o - V)}{dt} = K_C (V_o - V)$$

where K_L measures the rate of leak,
and K_C ,, ,, charging,

then the potential finally acquired by the instrument is equal to the real potential multiplied by $K_C/(K_L + K_C)$.

K_L/K_C is usually about $\frac{1}{16}$; that is, the instrument reads 6 per cent. lower than the true potential; but if this were constant it would be included in the exposure factor. There is, however, a possibility of a variation of this quantity K_L/K_C equal to its usual value. As the capacity of the instrument cannot be reduced nothing can be done to remedy this except to keep K_L as small as possible.

Review of Results.—From various causes (failure of the clock, etc.) a considerable loss of trace has occurred, but curves have been read as far as possible and days when there was a complete trace have been classified as follows by means of an electric character figure :—

0, denotes a day during which, from midnight to midnight, no negative potential was recorded.

1, denotes a day with excursions to the negative not amounting in the aggregate to more than three hours.

2, denotes a day with negative potential amounting in the aggregate to more than three hours.

Owing to the small range which could be registered on the sheet, the further subdivision into a, b, c days as at Eskdalemuir Observatory was considered undesirable.

Owing also to their incompleteness, the results are not being published in detail in this volume, but Tables I and II give a summary of the observations available.

TABLE I.

POTENTIAL GRADIENT (REDUCED TO LEVEL SURFACE): VOLTS PER METRE. MEAN VALUES FOR PERIODS OF SIXTY MINUTES, CENTERED AT THE EXACT HOURS, GREENWICH MEAN TIME.

	Jan.	*Feb.*	*Mar.*	*April.*	*May.*	*June.*	*July.*
3 h.	74 (7)	17 (3)	83 (4)	95 (15)	114 (25)	131 (25)	131 (21)
9 h.	71 (2)	7 (2)	49 (1)	99 (10)	96 (28)	153 (24)	170 (22)
15 h.	47 (8)	133 (6)	123 (9)	138 (19)	130 (24)	137 (26)	170 (21)
21 h.	115 (7)	58 (5)	125 (6)	127 (18)	176 (28)	170 (26)	186 (22)

Note.—The numbers in brackets are the numbers of observations used in forming the mean.

TABLE II.

POTENTIAL GRADIENT (reduced to level surface): DIURNAL INEQUALITIES (in volts per metre).

The departures from the mean of the day are adjusted for non-cyclic change.

"0" DAYS ONLY.

Equinox	− 18	− 24	− 2	− 4	+ 16	+ 6	− 15	− 34	− 27	− 26	− 23	− 14	− 6	− 6	0	+ 5	+ 10	0	+ 15	+ 29	+ 34	+ 46	+ 32	+ 9	..	4	140
Summer	− 4	− 3	− 20	− 5	− 6	− 4	− 5	+ 7	+ 5	− 9	− 14	− 21	− 8	+ 8	+ 4	− 1	− 2	− 2	+ 12	+ 20	+ 18	+ 20	+ 8	+ 2	..	28	166

In the present year perhaps the most noteworthy feature is the smallness of the range of the diurnal variation in summer, 41 v/m. as against 86 v/m. in the previous summer.

TERRESTRIAL MAGNETISM.

Notes on the Instruments.

Declination, horizontal and vertical force are recorded by the Adie magnetographs which were in use at Falmouth until 1912. The instruments had been stored for several years, but were reconditioned by the makers, and the declination and horizontal force instruments were tested at Kew before being installed at Lerwick in November, 1922.

The declination magnet has a unifilar suspension, and the torsion correction is negligible. The scale value is constant for all positions of the light dot on the sheet; throughout the year it was 1 mm. of ordinate to 1·93 minutes of arc. In the horizontal force instrument the magnet is maintained in a position approximately perpendicular to the magnetic meridian by torsion of the bifilar suspension. The vertical force balance consists of a single heavy magnet similar to those used for recording declination and horizontal force, and may be compensated for variations of temperature. Copper damping plates are fitted to each instrument and the recording mechanism is similar to that used at Eskdalemuir. The arrangement of the instruments in the magnetograph house is shown in Fig. 2 of the 1923 Year Book.

The chief instrumental defects encountered during the year were :—

(*a*) An occasional tendency of the trace, in the case of the H force instrument, to drift away from its base line.

(*b*) Unsteadiness of the vertical force system.

These troubles were not entirely overcome during 1926, but on the whole better and more continuous records were obtained than in former years. Towards the end of the year provision was made for more effective drying of the chamber, and this resulted in a great improvement in the behaviour of the instruments.

Adjustments to the horizontal and vertical force instruments were made on many occasions, and in consequence determinations of the scale values had to be taken frequently; the scale values have been assigned to periods between the discontinuities recorded, instead of for each month. The determinations are made by Broun's method, the deflecting magnet being placed in the " broadside on " position and at a distance of 55·9 cm. from the recording magnets. A larger deflection distance would render the error due to inequality of the distribution co-efficients for the H, D and V magnets less appreciable, but cannot be used owing to the restricted size of the magnetograph house. The double deflections produced are approximately 29 mm. for D, 31 mm. for H, and 19 mm. for V, giving scale values for the horizontal and vertical force instruments of about 7·7γ per mm. and 13γ per mm. respectively.

The records of declination, horizontal force and vertical force have been tabulated hour by hour. The values are read off by means of graduated celluloid scales, a value being the mean reading for 60 minutes centering at the hour.

Base values for the records are obtained from the results of absolute observations taken twice weekly. Horizontal force and declination are determined with Unifilar No. L 3951 (Cambridge Instrument Co.) using magnets 3951A and 3951C. The magnetometer is used on the centre pillar (No. 2) of the absolute hut, the azimuth of the fixed mark being taken as 8° 43′ 2″ east of south. Inclination is measured with Dover Circle No. 238 placed on the East pillar (No. 3), using $3\frac{1}{2}$ inch needles. In the deflection experiment three distances 25, 30 and 35 cm. are used for obtaining the distribution coefficients, the horizontal force being computed from the deflection at 25 cm. only.

Mean annual values of the P and Q correction have been derived from observations during the period March 1923 to 1926. An accident caused some change to the magnet in March 1923, and values for earlier months have been discarded.

The values during these years are as follows :—

Year.	P.	Q.	$\log_{10}(1+P/25^2+Q/25^4)$.
1923 (March–December) ..	−2·398	−14·36	$\bar{1}$·99831
1924	−1·236	−464·6	$\bar{1}$·99862
1925	−1·165	−875·9	$\bar{1}$·99821
1926	+1·225	−1711·2	$\bar{1}$·99895

The mean value of $\log_{10}(1 + P/25^2 + Q/25^4)$ employed in the reduction of all observations for 1926 was the mean of the values derived up to the end of 1925 namely, $\bar{1}$·99838. If the 1926 values are added, the mean for the total available period is raised to $\bar{1}$·99852. The adoption of this latter value would raise all the hourly values, monthly means, etc., as given in the tables by 2γ in the case of H and 7γ in the case of V.

As stated in the general remarks the walls of the magnetograph chamber are of concrete, 2 feet 6 inches in thickness. The diurnal variation of temperature within the chamber is comparatively small, the ranges of the mean diurnal variation in the various months having been as follows :—

Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
a.	*a.*	*a.*	*a.*	*a.*	*a.*	*a.*	*a.*	*a.*	*a.*	*a.*	*a.*
0·06	0·06	0·08	0·11	0·14	0·22	0·17	0·14	0·14	0·14	0·11	0·08

No correction for this diurnal variation of temperature has been applied to the diurnal inequalities or other data published in this volume. It will be noted, however, from the Tables, that the day to day change of temperature is sometimes considerable. On the average it is 0·31*a*. In October a case occurs of a fall of 5·1*a*. in six days, and in December one of 3·8*a*. in four days. These rapid fluctuations of temperature within periods of a few days obviously add considerably to the problem of satisfactorily determining base line values in the cases of the Horizontal and Vertical Force magnetographs. The temperature coefficient of the former is known with fair accuracy, being taken to be 6·1γ per 1*a*. In comparing curve readings with the results of absolute observations an allowance on this basis has been made ; and conversely in allotting base line values to given days the temperatures in the magnetograph chamber on these days—subject to a smoothing process—have been taken into account. Where resort to a complicated procedure of this sort is necessary, it would obviously be desirable to have absolute observations made more frequently than twice weekly. For another reason, namely that magnetic disturbance at Lerwick is so much more frequent and so much more considerable than at more southerly observatories, it would similarly be desirable to have very frequent absolute observations, with a view to the retention only of those made at times when the autographic records indicate a reasonably constant magnetic field. With the existing staff it has not, however, been possible to contemplate any increase of observing.

In the case of the Vertical Force, the magnetograph appears to be subject to a thermal hysteresis sufficiently large to render ineffectual any method so far tried of making allowance for the fluctuations of temperature in the chamber. It has not therefore been possible to bring into close accord with one another the base line values deduced from individual absolute observations. So long as these conditions exist the hourly values of vertical force must be regarded as of a somewhat lower order of accuracy than might be desirable. The diurnal inequalities are not of course subject to any appreciable uncertainty on this account ; the uncertainty only arises where for instance the mean value for a given day or series of days comes to be compared with that for another day or series of days.

There is, however, observable in some of the diurnal inequalities for quiet days a discontinuity which appears to arise from disturbance of the instrument at the time of changing charts—9.30 G.M.T. during the winter half of the year and 8.30 G.M.T. during the summer. Probably owing to the smallness of the chamber, the presence of an observer for a short time, as for instance during a scale test, causes an appreciable rise in temperature and this seems to be reflected in the record of vertical force in the form of a fairly rapid rise and afterwards a slow recovery to normal. The effect on the record is so characteristic that an approximation to the undisturbed curve can in general be drawn in with considerable confidence, and this has been done where the duration of the visit of an observer was sufficient to make the magnitude of the effect noticeable. It was not, however, realised until all data for the year 1926 had been worked up that the presence of an observer even for two or three minutes at the time of changing the charts could produce a measureable effect and one which on many days could be noticed if looked for. It has been decided not to attempt to eliminate it, in the results of the present year, because it is pretty certain that it is complicated by the existence of a mechanical effect, not definitely determinable.

Aurora.

From about September to April, a watch for aurora is maintained normally until about 23h G.M.T. each evening, and observations—as a rule at intervals of 15 to 20 minutes—are made of the northern horizon and of general meteorological conditions. The records form what is called the auroral log, a brief summary of which is given in Table 63. When any auroral display is observed, a second observer is called and detailed observations are maintained until the display subsides. So far these detailed observations have been mainly non-instrumental and have consisted in noting and making descriptions of the phenomena seen during the display. These notes are entered in a second log reserved for records of actual auroral displays. Extracts from this latter log may be obtained by anyone requiring the detailed information.

A general auroral table for Scotland (Table 64) is also included. This table has been compiled from the records of all stations at which climatological observations or weather logs are maintained. The observers at these stations, whilst noting occasions of aurora which they may happen to observe, do not in general maintain a special watch.

Notes on the Tables.

The hourly values of H, D and V, obtained as described above, appear in three of the four monthly tables. The variations in D, being expressed in minutes, may be readily converted to units of force (γ) of the component perpendicular to the magnetic meridian by multiplying by a factor which for 1926 is approximately 4.25. A rough comparison of the H, D, and V registrations with component registrations (geographical N and W, and V) as for instance at Eskdalemuir, can then be easily made. The mean value for the day is computed according to the expression :—

$$x = \left\{ \tfrac{1}{2} (x_0 + x_{24}) + x_1 + x_2 + \ldots\ldots\ldots\ldots + x_{23} \right\} / 24.$$

The letters "Q" and "D," prefixed to dates, denote the five quiet and the five disturbed days as selected at De Bilt.

In the fourth table for each month are given :—

(*a*) The values and times of the daily maximum and minimum and the values of the absolute daily range for each of the elements H, D and V.

(*b*) The value of ΣR^2 for each day. ΣR^2 is written for $R^2_H + R^2_D + R^2_V$ where R_H, R_D and R_V denote the absolute ranges in force for a calendar day of the components along and perpendicular to the magnetic meridian and of the vertical component, the ranges in declination having been for this purpose converted into units of force of the component perpendicular to the magnetic meridian.

(*c*) The "characteristic ratio" ρ, which is the ratio of the value of ΣR^2 for a given day to the mean monthly value of ΣR^2. This ratio is an index of the degree of disturbance or activity on a given day relatively to the other days of the month.

(*d*) The daily magnetic character figures, assigned according to the international scheme wherein "0," "1," "2," respectively, denote quiet, moderately disturbed, and highly disturbed conditions.

(*e*) The daily values of temperature in the magnetic chamber.

Mean diurnal inequalities of H, D and V on "all" days and on international quiet and disturbed days are given, for the months, seasons and year, in Tables 49 to 57.

In calculating diurnal inequalities the non-cyclic change has been eliminated on the assumption that its time rate is linear. The values of the range of the mean diurnal inequalities of the several elements on the three different types of day are brought together in Table 58, and the values of the non-cyclic change are given in Table 60. The "Average Departures," or mean values of the inequality taken irrespectively of sign throughout the 24 hours, are given in Table 59.

The mean values of the squares of the absolute daily ranges are summarized in Table 61.

In Table 62 appear for the months and year the mean values of N, W, V, D, I, H and Total Force T. The means of N, W, I and T are derived from the corresponding mean values of H, D and V, which are the means of hourly values on "all" days in the month or year.

Finally, in Tables 63 and 64 are given summaries of auroral observations obtained as already described.

Review of Results.

Mean and Extreme Values of the Magnetic Elements, 1926.—The mean values of the magnetic elements for the year 1926 are given in Table I. The values of H, D and V have been computed from the hourly values derived from the autographic records of "all" days, standardized by means of the absolute observations; those of N, W, I and T have been deduced from the values of H, D and V. For comparison are given the corresponding values for the year 1925, though these were somewhat differently derived, being the means of absolute observations only.

TABLE I.

Year.	H.	D. (West)	I.	N.	W.	V.	T.
	γ	° ′	° ′	γ	γ	γ	γ
1925.. ..	14621	15 17·7	72 37·2	14103	3857	46712	48947
1926.. ..	14618	15 2·8	72 37·1	14117	3795	46699	48933

The decrease in westerly declination from 1925 to 1926 (14′·9) slightly exceeds the rates for the two previous years, these having been 13′·8 for 1923–24 and 13′·0 for 1924–25.

Mean values derived from (*a*) international quiet days and (*b*) international disturbed days, are as follow :—(*a*) H, 14624 γ ; D, 15°3′·0 ; V, 46704 γ ; (*b*) H, 14605 γ ; D, 15°2′·5 ; V, 46683 γ.

The extreme values of H, D and V recorded during 1926 are given in Table II., but these values may have been exceeded at times when the light passed beyond the edges of the photographic paper ; this occurred rather frequently.

TABLE II.

Element.	Maximum.		Minimum.		Absolute Annual Range.
	Value.	Date, 1926.	Value.	Date, 1926.	
		d. h. m.		d. h. m.	
Horizontal Force..	15372γ	Jan. 26 .. 18 38	<13811γ	April 15.. Between 06 30 and 07 38	>1561γ
Declination ..	17° 28·5′	Feb. 24 .. 16 18	<12° 44·6′	Oct. 15 .. 23 10	>4° 44′·9
Vertical Force ..	>47329γ	Oct. 15 .. Between 22 28 and 22 54	45243γ	Oct. 15 .. 23 10	>2086γ

The range of 4° 44′·9 in declination is equivalent to a range of 1208 γ in the component of force perpendicular to the magnetic meridian.

Magnetic Character of the Year.—The mean sunspot number has increased in recent years from 5·8 in 1923 to 16·7 in 1924, 44·3 in 1925 and 62·4 in 1926. Coincident roughly with this increase there has been an increase of magnetic activity. Thus the mean absolute daily range of declination rose from 14·′9 in 1923 to 15′·4 in 1924, 18′·1 in 1925 and 25′·0 in 1926. But for individual months of 1926 the table below indicates no obvious relationship between the provisional sunspot numbers and the magnetic conditions.

	Jan.	*Feb.*	*Mar.*	*Apr.*	*May*	*June*	*July*	*Aug.*	*Sept.*	*Oct.*	*Nov.*	*Dec*
Provisional sunspot number	71·6	69·0	63·6	39·1	63·6	71·6	48·3	62·4	60·5	77·7	55·0	66·4
Mean absolute daily range of D	32·1	36·1	36·1	32·0	21·3	20·0	15·4	16·1	30·9	31·3	14·5	14·6
Mean ΣR^2 ($100\gamma^2$) ...	1850	2522	2262	1570	961	953	427	411	2343	3418	405	207

The values of mean absolute daily range for the months and seasons of the year 1926 are given in Table III., the ranges of declination in angle having for convenience of comparison been converted to units of force of the component perpendicular to the magnetic meridian. It will be seen that the ranges differ considerably from the corresponding Eskdalemuir values, the ratios of the annual mean ranges of Lerwick H to Eskdalemuir N, Lerwick D to Eskdalemuir W, and Lerwick V to Eskdalemuir V being respectively 1·4, 1·1 and 2·1.

It will further be noted that the seasonal behaviour of the ranges at Lerwick shows little resemblance to that at Eskdalemuir.

TABLE III.—ABSOLUTE DAILY RANGE. MEAN MONTHLY VALUES.

Month.	Mean absolute daily Range. 1926.			Mean daily Range expressed as percentage of Yearly Mean. 1926.

The frequency distribution of absolute daily ranges recorded in 1926 is shown in Table IV. A comparison with the corresponding figures for Eskdalemuir (Table V. on p. 153) indicates that ranges in excess of 200 γ are about twice as frequent at Lerwick as at Eskdalemuir.

TABLE IV.—FREQUENCY DISTRIBUTION OF ABSOLUTE DAILY RANGE.

TABLE V.—PRINCIPAL MAGNETIC DISTURBANCES RECORDED AT LERWICK, 1926.

Where the beginning of a disturbance has been marked by a "sudden commencement," the serial number is followed by an asterisk (*), and the time entered in the second column is that of the sudden commencement, estimated to the nearest minute. In other cases, the exact hour nearest the time at which disturbance may be regarded as having begun is entered in the second column. To the tabulated values of maximum and minimum, the following have to be added :—H, 14000 γ; D, 14°, V, 46000 γ.

No.	From	To	Horizontal Force.					Declination.					Vertical Force.

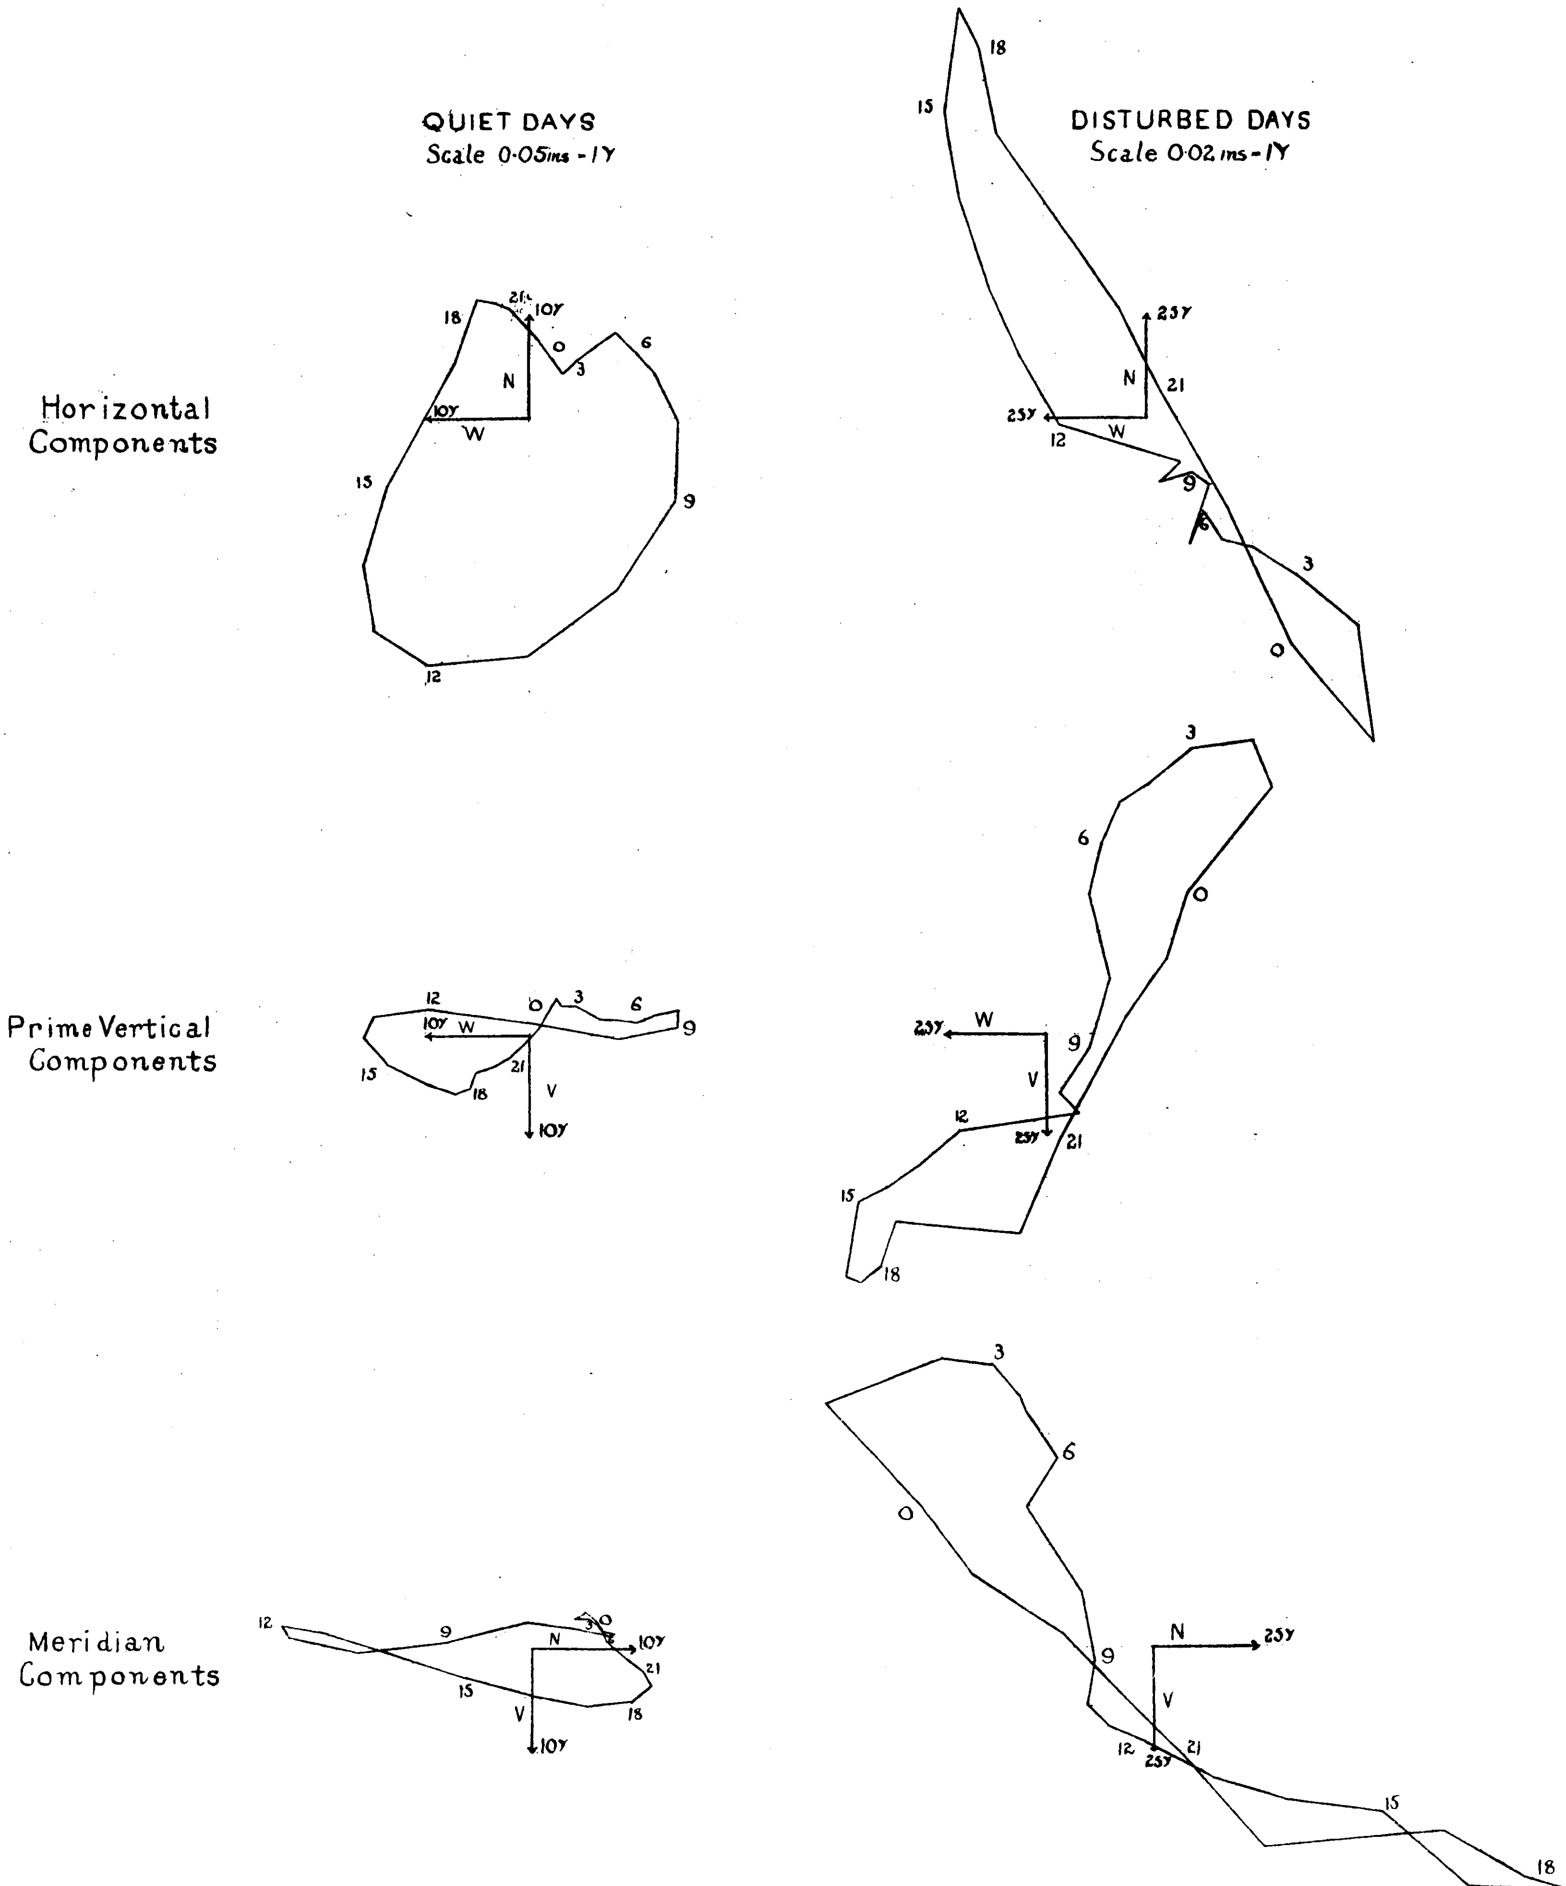
Vector Diagrams Illustrating Diurnal Variation in Magnetic Force on Quiet and Disturbed Days
Lerwick 1926.



P.1651A

Malby & Sons, Photo-Litho.

Diurnal Inequalities.—Considering first the inequalities for the international quiet days, we find in the five successive months June to October, as compared with 1925, a more or less diminished range of the inequality in the case of both D and H. In the remaining seven months (if we except April in the case of H, where the range shows a very slight reduction) the range of the inequality was increased. The ratios of the ranges for 1926 to those for 1925 in the various months were as follow :—

	Jan.	*Feb.*	*Mar.*	*Apr.*	*May*	*June*	*July*	*Aug.*	*Sept.*	*Oct.*	*Nov.*	*Dec.*
D ..	1·72	1·39	1·51	1·21	1·45	·77	·87	·93	·93	·89	1·10	1·01
H.. ..	2·24	1·35	1·14	·96	1·07	·94	·91	·64	·96	·82	1·06	1·21

In the case of the international disturbed days the range of the inequality was increased in all months except August and November for D and August, November, and December for H.

A comparison of the records of Eskdalemuir and Lerwick shows that the Declination inequalities at the two places for all, quiet and disturbed days are very similar in general appearance, although minor irregularities on the one set of values are not always reproduced on the other, or if so, only with diminished amplitude. Differences are more obvious on the Horizontal Force curves even on quiet days ; and the disturbed day inequalities in H in some months bear little resemblance to one another. In the case of Vertical Force the present year is the first year of observations to be published. In some months the quiet day inequalities are very different from those at Eskdalemuir and it will be seen from the table that the range of the inequality varies from little more than half the Eskdalemuir range in some summer months to over twice the Eskdalemuir range in January.

Ratio of the Range of the Inequality at Lerwick to that at Eskdalemuir. (1926).

On Plates I. and II. the diurnal behaviour of magnetic force is illustrated graphically, the representation in the latter plate being in the form of vector diagrams.

Magnetic Disturbances.—Particulars of the principal magnetic disturbances recorded at Lerwick during the year are given in Table V. In the Eskdalemuir Section will be found a similar list which deals with the same disturbances as recorded at that Observatory.

In so far as " sudden commencements " are concerned it has to be remarked that within the limits of accuracy of measurement and registration, these events appear to occur simultaneously at the two Observatories.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

† Mean of 26 days; 19th and 20th omitted. * New suspension fitted.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

7. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + **February, 1926.**

* Max. between 14·20 and 15·02 or 16·12 and 17·26; min. between 21·00 and 21·07 or 23·14 and 23·20.

§ For explanation *see* pp. 28–29.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

† Mean of 30 days; 2nd omitted. * Lighting circuit tested and light adjusted.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

* Lighting failed. † Mean of 29 days; 5th omitted.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

† Mean of 29 days; 5th omitted. * Lighting failed.

§ For explanation *see* pp. 28–29. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

* Clock stopped. † Mean of 29 days; 13th and 14th omitted.

§ For explanation see pp. 28-29.. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

21. Lerwick. (H.) **June, 1926.**

* Min. between 22·22 and 22·39 or 23·40 and 24·00.

§ For explanation see pp. 28–29.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

25. Lerwick. (H.) 14,000 γ (·14 C.G.S. unit) + **July, 1926.**

§ For explanation *see* pp. 28–29. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

TERRESTRIAL MAGNETIC FORCE: HORIZONTAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

29. Lerwick. (H.) 14,000 γ (·14 C.G.S. unit) + **August, 1926.**

* Adjustment of instrument. † Mean of 30 days; 10th omitted.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

§ For explanation *see* pp. 28–29.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

33. Lerwick. (H.) 1,4000 γ (·14 C.G.S. unit) + **September, 1926.**

* Drums not rotating. † Mean of 29 days; 20th and 21st omitted.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

39. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + **October, 1926.**

* Drums not rotating. † Mean of 29 days; 20th and 21st omitted. § For explanation see pp. 28–29.

‡ Min. on 15th between 00·01 and 02·20, or 19·45 and 20·00 or 22·00 and 24·00. †† Min. on 16th between 00·01 and 01·20 or 01·58 and 02·12.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

* Clock stopped. † Mean of 28 days; 3rd and 4th omitted.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

43. Lerwick. (V.) 45,000 γ (·46 C.G.S. unit) + **November, 1926.**

* Clock stopped. † Magnet not moving freely. ‡ Drying agent renewed. ** Mean of 26 days; 3rd, 4th, 11th and 25th omitted.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57. § For explanation *see* pp. 28–29.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

* Suspension broken. ‡ Mean of 29 days; 12th and 13th omitted.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

47. Lerwick. (V.) 46,000 γ (·46 C.G.S. unit) + **December, 1926.**

§ For explanation *see* pp. 28–29. † Trace drifting. ‡ Mean of 25 days; 2nd, 3rd, and 11th to 14th omitted. * Magnet removed for examination.
Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 52–57.

Departures from mean of the day adjusted for non-cyclic change.

HORIZONTAL FORCE (*all days except Feb.* 19, 20; *Mar.* 2; *April* 5; *June* 7, 8; *Oct.* 20, 21; *Nov.* 3, 4; *Dec.* 12, 13).

29 ...	
30 ...	
31 ...	

In the interests of brevity there have been omitted from the table above all dates on which the sky throughout the evening remained completely overcast and on which, therefore, no opportunity arose of determining whether or not aurora occurred. The nights on which aurora was actually seen are indicated by the symbol Ш. The nights on which aurora was not seen, despite at least an occasional interval of more or less clear sky, are indicated by the symbol ... ; in the latter case also, remarks on the weather are added to assist the reader in judging how far the fact of no observation of aurora may be taken as indicating that there was not actual aurora. A full description is available of the auroral phenomena observed.

INTRODUCTION.

SITE.

The Observatory, which was established in 1868, is housed in the top floor of the Cromwell Tower of King's College in Old Aberdeen. The College lies on a plain gradually rising from the sea from which it is distant about 1 mile (1·6 km). There are no serious irregularities of surface in the vicinity excepting the two river valleys of the Don and the Dee. To the north, at a distance of about 1 km the Don flows eastwards to the sea ; the Dee flows into the sea at a distance of about 3 km. to the south-east of the College. Between the College and the sea is a golf course covered for the most part with grass. Westwards is the High Street of the Old Town and beyond this there is another street. Further west grass pasture extends for about one kilometre. Southward are some open spaces beyond which the modern town is reached. The enclosure in which the Stevenson screen, the Beckley and check rain-gauges and the grass minimum thermometer are exposed, lies to the north-east of the Observatory at a distance of about 50 metres. The "North-wall" screen in which the recording thermometers are exposed is erected on the wall outside the north window of the uppermost story of the Observatory. The nature of the soil and sub-soil is loam and sand.

Plans showing the position of the Observatory relative to the City of Aberdeen, and the general arrangement of the College Buildings, and also photographs, will be found in the Introduction to the Observatories' Year Book 1923.

Change of value adopted for height of Station above Mean Sea Level.—Consequent upon a careful redetermination of the height of the Station above Mean Sea Level a new value has been adopted for this height for all purposes, as from the 1st January, 1925. The value for the station level is now 13·4 m., and that for the height of the barometer-cistern is 26·0 m., in place of the former values of 14·0 m. and 26·8 m. respectively.

METEOROLOGY.

The elements dealt with in the following tables are :—Atmospheric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, earth temperature and minimum temperature on the grass, together with a diary of cloud and weather.

The instruments from which values of the above elements have been obtained and the methods of tabulating the records are described in the General Introduction to this volume. The following additional information refers especially to Aberdeen.

Pressure and Temperature.—The barograph, standard Kew barometer and thermograph are housed in the uppermost story of the Observatory. The pressure scale value of the barogram is 1 mm. on the paper = 0·85 mb., when the paper is at normal atmospheric humidity. In similar circumstances the time scale is 9·3 mm. = 1 hour. The records of the photobarograph are standardized

* These values differ slightly from those given in former years. See note above.

by means of control readings taken from Fortin Standard Barometer M.O. 273. The N.P.L. certificate of this barometer shows a correction varying from –0·1 mb. to –0·2 mb. throughout the scale, at a temperature of 273 a. ; and this correction has been applied to the control readings.

The recording thermometers are placed in the North-wall screen already referred to. The scale value of the wet bulb thermograph record is 1° absolute = 3·20 millimetres on the paper ; for the dry bulb thermograph the scale value varies slightly with the temperature, but is approximately 1° absolute = 3·4 millimetres. The time scale is 1 hour = 9·23 millimetres. Reading of the photothermograms is done by means of glass measuring scales, the records being standardized by control readings from Standard Thermometers M.O. 1698 (dry bulb) and M.O. 1697 (wet bulb). These thermometers have corrections, varying at different parts of the scale, of between –0·1 a. to +0·2 a. ; these corrections have been applied to the control readings. The heights of the barometer cisterns and of the bulbs of the thermometers are given at the top of the appropriate tables.

Rainfall.—The recording instrument in use is Beckley rain-gauge No. 2 with an area of 101·1 square inches (653 cm^2.). The procedure adopted in tabulating the records is similar to that described in the General Introduction and calls for no comment. Control is by check gauge M.O. 167.

Humidity.—On those occasions when the temperature of the wet bulb has been 273a or under, the relative humidity has been obtained from the records of a hair hygrograph. This instrument is accommodated in a small louvred screen which rests on top of the Stevenson screen and is securely fixed to it. The hygrograph is 11·6 metres below the level of the thermograph bulbs in the North-wall screen, and in using its records an appropriate adjustment is made.

Sunshine.—The sunshine recorder (Campbell-Stokes type) is exposed on the small circular tower on the Observatory roof on which the Robinson Cup Anemograph is erected. It is rigidly held by lead flaps soldered to the lead roof. The exposure is excellent ; the only obstruction is a flagpole to the east, of angular diameter about 1°, which may obstruct 0·1 hr. record about 7h between April and September. This loss has been allowed for, whenever practicable, in tabulating the records. In computing the percentage duration of sunshine the actual possible values for each day of the year 1926 have been employed, a departure from the practice of previous years.

Wind-Speed and Direction.—As stated in the General Introduction, the values for 1926 are tabulated from the records obtained by the Dines Pressure-tube Anemograph. This instrument is one of the "standard mounting" type, and is situated in a field about ½ km. east of the Observatory. The exposure is a more open one than is that of the Cup Anemograph, the records of which were tabulated in previous years. The effect of this exposure upon the recorded values is given in the Table in the General Introduction.

In a few instances where the records of the Pressure-tube instrument have been defective, the required values have been obtained from the records of the Cup instrument, a suitable adjustment of such values having been made in accordance with the data given in the above-mentioned table. Values thus obtained are entered in italics.

Temperature in the Ground.—This is recorded by a thermometer (unnumbered), which is kept at a depth of 124 cm. (four feet). At Aberdeen the thermometer is carried in a slot near the end of a long bar of wood, about three inches (7·5 cm.) square in section. This bar fits closely into a wooden sleeve, sunk vertically into the earth, so that the bulb of the thermometer is at the required depth. The thermometer itself is enclosed in a glass tube, and its bulb is embedded in paraffin wax so as to render the thermometer insensible to sudden changes of temperature. This allows of its being drawn to the surface and read before the temperature of the bulb has time to change appreciably. As underground temperature changes very slowly, the loss of sensitiveness, resulting from the coating of wax, does not lead to inaccuracies in the determination of the temperature of the earth. The thermometer is read at 9h each morning. The thermometer has a correction of −0·2 a.; this correction is applied to all readings.

Minimum Temperature on the Grass.—The grass minimum thermometer is exposed in the enclosure on two wooden pegs about 4 cm. above grass. It is set at 18h and read at 7h, the reading being entered to the day of observation. There is a correction, varying between 0·0 a. and 0·05 a., which is applied to the readings.

Cloud.—In connection with the observations of cloud-forms it might be well to indicate the practice adopted at Aberdeen in dealing with the types Nimbus and Strato-cumulus, in view of the fact that there exists among meteorologists some divergence of opinion upon these types, and also because suggestions have been made for a prospective modification in the definitions of the International Classification.

In the case of Nimbus it is the custom at Aberdeen to enter " Nb " on all occasions when the cloud layer from which rain is falling is obviously dense and has developed from A-St, even when no Fr-Nb is visible below it. This is done because it is not always certain to the observer whether the cloud layer is actually uniform low A-St developed as far as rain, or whether a slight mist-film exists below the ragged Fr-Nb., obscuring the latter from view, and thus giving it the appearance of a uniform featureless sheet. (It is probable that in future a suggestion will be made to extend the definition of A-St in the International Classification to include the dense rain-giving layer which develops from the normal A-St.)

On occasions when the low anticyclonic stratus degrades into drizzle or light rain, it is customary at Aberdeen to enter Nb-St (Nimbo-stratus). The entry " St " is reserved for the type of cloud found generally in dry anticyclonic weather.

The entry St-Cu includes only the cloud-forms as defined under that heading in the International Classification, though some of the entries might equally well have been termed A-Cu. It does not, however, include the bases of closed-up cumulus clouds, nor groups of cumulus arranged in lines.

Visibility.—In the subjoined table there is given a list of the objects used for the determination of the degree of visibility, together with their distances and bearings from the observation-point, which may be taken as the roof of the Observatory tower, the N.E. corner thereof being used for the nearer objects.

The range of visibility from the Observatory is somewhat limited by the high ground surrounding the city. From S.E. through S. to N. the distance of the visible horizon is between 2 and 4 miles (4 to 7 km.), but in the N.W. a higher hill, at a distance of 5 miles (8·5 km.), rises above the nearer ridges. To the N.N.E. however there is a clear view of the coast-line as far as Cruden Scaurs, where the coast consists of cliffs over 100 feet high, and is nearly 19 miles (30 km.) distant. From N.N.E. to S.E. there is only the sea-line as horizon, which from the height of the Observatory tower is about 10 miles (16 km.) distant.

Definite objects exist at standard distances from A to H, but from I to M there are no definite objects, though there are adequate identification marks for K and L. Owing, however, to these marks being on the sea-coast, and to the generally clearer visibility to the seaward side of the Observatory, it has been deemed advisable to employ small letter entries for all visibility distances that are not definitely landward estimates. The distances I and J are based upon estimates between other available distances. During darkness the estimates depend upon personal judgment, and upon the degree of obscuration, and alteration in the colour, of the surrounding lights of the town.

Review of Meteorological Results.

Pressure.—The most noteworthy feature of pressure was the remarkable fluctuation at the end of the year. Up till October the departure from the normal monthly values varied between 1 mb. and 5 mb., but in November there was a rapid decline to a deficit of 12 mb., followed in December by a still more rapid rise to an excess of over 13 mb.

The monthly and seasonal mean diurnal inequalities have been analysed harmonically this year for the first time, and the results are given in the following Table. The unit employed in calculating the values for the individual months was ·01 mb., that for the seasons and the year was ·001 mb. The phase-angles are reduced to Local Mean Time.

The inequality is supposed to be given by the expression—

$$c_1 \sin (15t^\circ + a_1) + c_2 \sin (30t^\circ + a_2) + \ldots\ldots$$

t being the time in hours since midnight.

Equinox	·180	136	·264	144	·048	353	·035	347
Summer	·050	147	·223	139	·032	145	·009	311

Note.—*Winter* comprises the four months, January, February, November, December; *Equinox* the months March, April, September, October; and *Summer* May to August.

The values shown in the above Table present the usual features of such an analysis. In the 24-hour term the amplitude C_1 and phase-angle α_1 vary irregularly from month to month, whereas, in the 12-hour term, C_2 and α_2 show much more consistent values. In the 8-hour term C_3 shows higher values in winter than in summer, while the phase-angle α_3 is almost reversed. The amplitude of the 6-hour term is in most months small and its phase-angle is variable from month to month.

The months of February and November show marked similarity in the values of the amplitudes of the four terms, and a fair approach in the phase-angles of the first three.

Temperature.—Temperature was somewhat in excess of the normal value during the greater part of the year, March showing an increase over the normal of 1·6a., but in October there was a deficit of about 2·0a. The greatest accumulated excess occurred in the first four months of the year.

Rainfall.—Up to the end of August there was a deficit of about 27 mm., but the months of September, October, and November yielded an excess of about 148 mm., so that despite a further deficit of 58 mm. in December, the year on the whole was a wetter one than usual by about 63 mm.

Sunshine.—Sunshine was distributed rather unusually throughout the year, the first six months all showing percentages below the normal, while in the second half of the year every month had an excess. It is also worthy of note that the very wet months of October and November had very considerable excesses of sunshine.

Wind-Speed and Direction.—The year showed no marked departures from the normal; even the months of January and November—both of which had very low pressure, and showed an average diurnal range of over 10 mb.—were not remarkable for high wind-velocities; gale force was reached only on one day—25th October.

General.—The year as a whole showed a dry, warm, but dull spring; a dry, rather warm and bright summer; a very wet, rather cool, but bright autumn; while the winter months of January and February were wet and dull, and December dry and bright, but all of them were warmer than is normally the case. The month of June showed a very close approach to normality in the various meteorological elements.

Readings in millibars at exact hours, Greenwich Mean Time.

65. Aberdeen : H_b (height of barometer cistern above M.S.L.) = 26·0 metres. **January, 1926.**

* Computed from the mean temperature and mean relative humidity. † Mean of the column. ‡ Mean of the row.

Percentages at exact hours, Greenwich Mean Time. Determined as explained on page 14.

101. Aberdeen : North Wall Screen on Tower : h_t (height of thermometer bulbs above the ground) = 12·5 metres. **July, 1926.**

110. Aberdeen. NOTES ON RAINFALL. **1926.**

Notable Falls of the Year.—The chief fall was that of 43 mm. on September 20th, mentioned below. The heaviest rate of fall occurred on 24th July when 5 mm. fell in 35 min.

Dry Periods.—(Periods of 7 days or over with no rainfall or with trifling falls.)

Mar. 11—April 14. A rather dry period; only 17 mm. falling in 35 days. March was a dry month, with a total fall of 25 mm.
April 1—13. In 13 days 2·5 mm. of rain fell.
July 1—18. In this period there was no rain from the 11th to the 18th. The total fall in the 18 days was 1·1 mm.
July 29—Aug. 4. No rain for 7 days.
Aug. 24—Sept. 9.—Period of 17 days with only 0·9 mm. of rain. No rain fell from Aug. 24th to Sept. 3rd.
Dec. 6—12. No rain for 7 days.
Dec. 22—31. Only 0·3 mm. fell in 10 days. This spell lasted 13 days—up till 3rd January, 1927. December was the dryest month of the year; only 24 mm. of rain fell.

Wet Periods.—(With notes of the heavier rates of fall.)

Feb. 3—8. Over 57 mm. of rain fell in this period.
April 14—30. A "rain-spell" of 17 days with 60 mm. of rain.
July 19. In 19 hours 35 mm. of rain fell, of which 31 mm. fell in 15 hours.
Sept. 20. The heaviest individual fall of the year—43 mm. in 12 hours.
Oct. 8—9. A total of 36 mm. fell.
Oct. 12—13. A total of 35 mm. fell.
Oct. 22—30. During this period 42 mm. of rain, sleet and snow fell intermittently. October was the wettest month of the year, with 143 mm.
Nov. 2. A total of 34 mm. of which 20 mm. fell in 13 hours.
Nov. 19—20. Intermittent fall of 32 mm.

Amounts in millimetres, for periods of sixty minutes, between the exact hours, Greenwich Mean Time.

111. Aberdeen : H_r (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + h_r (height of receiving surface above ground) = 13·4 metres + 0·6 metres. **January, 1926.**

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) =8 metres + 13 metres.

January, 1926.

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 8 metres + 13 metres.

March, 1926.

INTRODUCTION.

SITE.

Eskdalemuir Observatory, some 3½ miles (5½ kilometres) north-north-west of Eskdalemuir Parish Church in the county of Dumfries-shire, is situated on a rising shoulder of moorland which is bounded on the east by the road which leads north to Ettrick and Selkirk, on the west by the small Davington Burn, and at the southern extremity by the small hamlet of Davington.

The hillside in the immediate vicinity of the Observatory slopes generally from the north-west to south-east. The mean height above sea level of the Observatory site is about 800 feet (244 metres). Cassock Hill, slightly more than a mile distant to the north-west, is 1,205 feet (367 metres), while the bench mark at Davington School, ¼ mile (0·4 km.) to south-east, is 699 feet (213 metres) above M.S.L. To the east the ground slopes fairly rapidly to the valley bottom, the level of the Ettrick road at a point about ¼ mile (0·4 km.) east of the underground magnet house being 682 feet (208 metres). The River White Esk is rather less than ½ mile (0·8 km.) to the east. Immediately beyond the river, and almost due east of the Observatory, Dumfedling Hill rises to a height of nearly 1,200 feet (366 metres) above M.S.L. Some 4 or 5 miles (8 km.) to the north is a high ridge, following approximately the boundary between Dumfries-shire and Selkirkshire, the highest point of which is Ettrick Pen (north-north-west) 2,200 feet (670 metres) above M.S.L. Rather more than half a mile (0·8 km.) to the west, and beyond Davington Burn, the ground rises to 1,040 feet (317 m.), and reaches nearly 1,200 feet (366 m.) half a mile (0·8 km.) further on. To the south and south-south-east the Observatory commands a view of the White Esk Valley as far as Hartmanor, 4 miles (6½ km.) distant, and beyond that the upper slope of Cauldkine Hill, about 10 miles (16 km.) distant, is visible. The surrounding country is bare and wild and there are but few trees to relieve the monotony of the grass-covered hills and moorland.

Within the Observatory grounds the soil is peaty and in many places is more or less boggy at all seasons. Some two feet, or less, below the surface a clay-like substance containing soft rock is encountered. The local geological formation is described as " rock of the Tarannon Llandovery series traversed by igneous dykes."

The selection, in the early years of the century, of this isolated site for the Observatory was dictated by the desire to reduce to a minimum the possibility of artificial magnetic disturbance due to electric traction and power circuits, and in this connection it may be noted that there is no town, industrial centre, or point of railway within a radius of 9 miles (14½ km.) from the Observatory.

Photographs, site plan, and a brief description of the Observatory will be found in the Introduction to *The Observatories' Year Book*, 1923.

METEOROLOGY.

The elements dealt with in the following tables are :—Atmospheric pressure, air temperature, humidity, rainfall, sunshine, solar radiation, wind speed and direction, and minimum temperature on the grass. There is also a diary of cloud and weather.

Notes on Instruments.

Brief descriptions of the recording instruments and of the methods of tabulating the records, with notes on the information contained in the Tables, are given in the General Introduction to the Tables. The following particulars, which refer specially to Eskdalemuir, are to be regarded as amplifying the information contained therein. References to full accounts of other instruments used at Eskdalemuir appear below.

Pressure.—The standard mercury barometer, Kew pattern, is situated in a north window embrasure on the ground floor of the main building.

The photographic mercurial barograph is situated in the east room of the underground magnet house. The daily range of temperature to which the instrument is subject is normally less than 0·05°C., the annual range being about 4°C. The scale value of the records is 1 millimetre on the paper = 0·85 millibar, and the time scale is 9·1 millimetres on the paper = 1 hour.

As in former years, records of pressure were also obtained from (*a*) a Dines float barograph[1], of which a description will be found in the Introduction for 1923, and (*b*) a Richard barograph, pen recording, the records of which are changed weekly.

Temperature.—The photographic thermograph and the standard mercurial thermometers, dry bulb and wet bulb, are situated in a wooden hut, provided with louvred sides and double roof, which is some 200 feet (60 m.) north-north-east of the main building. The installation is similar to that described on p. 10, except that a special enclosure is provided inside the hut to accommodate the optical and photographic arrangements.

The scale values of the thermograph records are 1° absolute = 2·79 millimetres and 2·44 millimetres on the paper for the dry and wet bulb records respectively, while the time scale is 1 hour = 9·20 millimetres.

As auxiliary recorders of temperature there are, in the same louvred hut :—

(*a*) A psychrograph, pen recording, which is in effect a bimetallic spiral thermograph with two spirals, one of which is kept dry and the other wet. The records are of 24 hours' duration.

(*b*) A bimetallic spiral thermograph, of which the record is changed every week. It is described in the *Meteorological Observer's Handbook.*

Humidity.—In addition to the dry and wet bulb thermograph described above there is a Richard hair hygrograph which is situated in a Stevenson screen about midway between the louvred hut and the main building.

As is stated on p. 14, the records from this instrument are utilised when the wet bulb reading does not exceed 273a. On the records obtained in 1926 a change of 10 per cent. in relative humidity is represented by about 0·8 centimetre, the time scale being 1 hour = 3 millimetres.

Rainfall.—The recording instrument is a Beckley self-registering rain-gauge, which is described on p. 11. The time scale of the record is 1 hour = 9·24 millimetres on the paper and the rain scale has a magnification of 3·35. The instrument has been in use at Eskdalemuir since 1908 and was originally installed at Fort William in July, 1890.

[1] In December, 1924, this instrument was removed from the underground magnet house, overhauled, and installed against the north wall of the laboratory on the ground floor of the main building.

The conical part of the gauge funnel is surrounded by a cylindrical copper casing lined with asbestos on the inner side and of diameter equal to that of the funnel, viz. 11·27 inches (28·6 cm.). Within the enclosure so formed is a gas jet, and a flame of suitable dimensions is maintained, as circumstances dictate, to melt snow which may be collected.

The gauge is surrounded by a circular turf wall or dyke, the top of which is on a level with the rim of the gauge; the external and internal diameters of the dyke being 11·5 feet (3·5 m.) and 7 feet (2 m.) respectively.

A standard 8 inch (20·3 cm.) rain-gauge is situated some 24·5 feet (7·5 m.) to the east of the Beckley gauge and is surrounded by a turf dyke of similar dimensions. Readings of amounts of rain received in the 8 inch gauge are made at 7h and 18h G.M.T. It is customary to adjust the indications of the recording gauge to agree with the readings of the standard check gauge.

Sunshine.—The record of sunshine is obtained from a Campbell-Stokes recorder described on p. 11.

The recorder is fixed on a stone pillar and has a reasonably free exposure, the chief obstacles being hills to east and west. The elevation of hills between 70° and 110° east of south varies from 2·5° to 5°, while between 50° and 135° west of south the high ground varies in elevation from 3° to 4·4°, being generally about 3·5°. As sunshine can be recorded when the sun is 3° above the horizon only in the most favourable circumstances, it appears that the loss of record occasioned by the neighbouring high ground is of relatively small extent and is confined mainly to a possible defect of record at the beginning of the day during a few weeks centred about the equinoxes.

Solar Radiation.—Measurements of the intensity of radiation received from the sun by a surface which is normal to the line drawn from the instrument to the sun are effected by means of an Ångström compensating pyrheliometer.[1] The intensity of radiation is expressed in milliwatts per square centimetre (1mw. per sq. cm. = 0·01435 gramme calorie per sq. cm. per minute). In addition, the value is given of the function (p/p_0) sec Z, in which p is the barometric pressure at the observatory in millibars at the time of the observation, p_0 is 1000 millibars, and Z is the zenith distance of the sun. This affords a measure of the mass of atmosphere which the solar radiation has had to penetrate before reaching the earth. Entries in the column headed " Sky " are intended to show the presence or absence of haze, mist or cloud in the direct path of the solar radiation recorded.

Wind.—A Dines tube anemograph, furnished with direction recorder, is situated in the main building. The vane-head is 15 metres above a tangent plane to the slope of the hillside and approximately 7 metres above the general level of the roof of the building.

The anemograph vane in use throughout 1926 is that which was introduced in August, 1925. It differs from that formerly in use in that the greatest dimension of the fin is vertical instead of horizontal, and that the cross-section of the fin is of aerofoil shape. A twin-lever direction recorder has been in use since June, 1925. In this instrument a pen is carried by each of two pivoted arms, upper and lower. A projection from each arm engages with a flange of a dual helical device cut in a short cylinder (of vertical axis) which rotates with the vane, being connected thereto by a vertical " rod " consisting of steel tubing 1·5 cm. external diameter. During the interval June 2 to June 7, 1926, the tubular mast which supports the anemometer head was adjusted in order to reduce the possibility of contact between the direction rod and the inside of the mast. On December 13, a flexible coupling was introduced between the direction recorder and the direction rod. This modification has resulted in increased sensitiveness of the direction record with light winds.

[1] For description see *The Observer's Handbook*, 1921, Ed., Meteorological Office, London; *Astrophysical Journal*, Vol. IX, 1899; *Actes de la société royale des Sciences d'Upsal*, 1893; also *Geophysical Memoirs*, No. 21 (1923), Meteorological Office, London.

Apart from the surrounding hills, the exposure of the vane-head is tolerably free in all directions save to the west where at a distance of some 130 feet (40m.) is a rather large building, of which the height is somewhat greater than that of the main building. With winds from nearly due west the direction records show markedly greater turbulence than with other winds.

Minimum Temperature on the Grass.—The thermometer used for readings of grass minimum temperature is of the spirit type with index; and when exposed, between 18h and 7h G.M.T., is supported at a height of one or two inches (4 cm.) above close-cropped grass a few metres from the louvred thermometer hut.

Visibility.—The descriptions of the selected visibility objects, together with the distances and bearings from the point of observation, are given in the subjoined table. Auxiliary objects and guide criteria are given in brackets. Certain of the nearer objects may be identified by reference to the photographs and site plan published in *The Observatories' Year Book*, 1923. Unless otherwise stated, the distances and bearings are with reference to certain of the windows on the upper floor of the main building.

The situation of the Observatory and the nature of the immediate surroundings allow of only a very limited choice of objects. The objects A to D are situated mainly to the north, while the more distant objects are toward south to south-east, *i.e.*, down valley. Four miles or so to the north of the Observatory the hills rise in places to rather more than 2,000 feet above sea level and at times visibility in this direction is distinctly less than towards south. On other occasions the hills to the north are visible, but nearer objects down the valley are invisible owing to valley mist. With the exception of the cottage at Finglandshiel, and Cauldkine Hill, the objects more distant than D are below the level of the Observatory. There are no objects at distances which approximate sufficiently closely to the standard distances for objects H, J, and K. When it is estimated that the range of visibility is such that objects at these standard distances would be visible the corresponding small letter entries are made in the Diary of Cloud and Weather. The estimates of visibility in the dark depend largely on the judgment of the observer. There are no lights other than those in the Observatory buildings and in two cottages within a radius of one mile.

Corrections to Instruments in Use in 1926.

The corrections to the instruments in use during 1926 are given below. In all cases the corrections are those given in the certificate of examination issued by the National Physical Laboratory. With the exception of the grass minimum thermometer the corrections here given have been applied in 1926 and in previous years. The date on which each of the instruments mentioned was brought into use is given for purposes of reference.

Notes on the Meteorological Summaries.

The number of years for which meteorological results are available is insufficient as yet to yield a completely representative set of normal values. Although certain meteorological data are available for 1909 and 1910 it is only since 1911 that the reductions have been made in accordance with an approximately uniform plan. In the following notes the normal or average values referred to are for the period 1911 to 1926, unless otherwise stated.

Pressure.—The mean pressure at station level for the year differed by less than 0·1 mb. from the normal value. The departures of monthly mean values from the corresponding normals were not remarkable except in November and December; the November mean, 970·43 mb., being 11·6 mb. below, and the December mean, 995·17 mb., nearly 16 mb. above the corresponding normal value. A monthly mean value in excess of 995·17 mb. occurred only once in the previous 15 years, while there have been only three monthly mean values less than that for November, 1926. The highest instantaneous pressure yet recorded, 1018·0 mb., occurred on December 24, when the centre of a large and intense anticyclone was moving slowly westward across the north of Scotland. The lowest value for the year, 937·7 mb., occurred on November 20, the whole of the British Isles being influenced at that time by a complex deep depression. In no previous year was the absolute annual range of pressure as high as that in 1926, viz., 80·3 mb. The absolute range of pressure within a calendar month varied from 60·1 mb. in October to 31·1 mb. in May. The highest and lowest monthly means of the absolute daily range of pressure were 10·5 mb. and 4·6 mb. in January and May, respectively. The mean values of this quantity in February, April, May, September and December were from 17 to 24 per cent. below, and in October and November were 18 and 20 per cent. above, the corresponding average values. The mean absolute daily range for the year as a whole was smaller than in any of the previous 15 years.

Pressure (Diurnal Variation).—In comparison with the ranges of the mean diurnal inequality in previous individual years the range in 1926 is rather noticeably low in February, March, May, and high in July. The forenoon maximum in the diurnal inequality is not very well developed in January, February, April and July, but is rather prominent in October and December. The inequalities for September and October are alike in that the early morning minimum is comparatively prominent whereas the afternoon minimum is less marked than is usual. In respect of the rather poorly marked forenoon maximum and the approximately equal development of the morning and afternoon minima the inequalities in April, 1919, 1920, 1923 and 1926 are very similar. In eight months of 1926 the principal maximum occurs from one to three hours before midnight. From February to September, inclusive, the time of occurrence of the principal maximum is close to that in the normal inequality (1911-20). In half of the months the principal minimum falls at 16h or 17h, and in the other half at 4h or 5h. In January, February, April, June, July and November the time of the principal minimum approximates closely to that shown in the normal inequality. The principal maximum in the inequality for January is at 2h. There are indications of a third maximum at from 1h to 3h in the inequalities for March, November and December.

The results of the harmonic analysis of the monthly and seasonal mean diurnal inequalities for 1926 are given in the accompanying table. For purposes of comparison the corresponding data (1) derived from the mean inequalities for the period 1911–20 are also given. In computing the Fourier co-efficients for the individual months of 1926 the unit employed was ·01 mb.; but for the seasons and the year the inequalities were taken to ·001 mb., and in these cases the values of c_1 etc. are given to three decimal places. Although for 1926, as for recent years, the phase angles are given to the nearest 1°, this course is scarcely justified, at least for the third and fourth components, by the character of the data from which the harmonic coefficients for the months and seasons of a single year are computed. The phase angles α_1 etc. given in the table below refer to Local Mean Time, whereas in the corresponding tables for 1922 and 1923 the phase angles refer to Greenwich Mean Time.

The values of c_1 and α_1, for individual months of 1926 show considerable irregularity, but, judging from the ratio of the arithmetic mean of the monthly values of c_1 to the value of c_1 for the year as a whole, the variability in phase of the 24-hour term was less than in 1925. The arithmetic mean value of c_1 has decreased continuously from 1922 to 1926. A more pronounced decrease is seen in the value of c_1 for winter during these years. In the first half of 1926 the amplitude of the

(1) "On the Diurnal Variation of Atmospheric Pressure at Eskdalemuir and Castle O'er, Dumfriesshire," by A. Crichton Mitchell, D.Sc., *Quarterly Journal of the Royal Meteorological Society*. Vol. L., No. 210, April, 1924.

12-hour term tends to be less, and in the second half greater, than the value found for 1911-20. The predominance of the September and October values of c_2 is more pronounced than is usual. In January α_2 is less than the normal by 21°, while the December value exceeds the normal by 12°. These, however, are the only departures from normal exceeding 10°. The seasonal values of c_2 and α_2 are in very close agreement with the normals. The annual variation in the 8-hour term in 1926 is fairly similar to that for 1911-20, the amplitude being greatest in winter and small at the equinoxes when the transition in phase takes place. Excepting the value for summer, the seasonal values of c_3 are in excess of normal. The phase of the 8-hour term for summer is almost exactly opposed to the phase for winter and equinox. The four equinoctial monthly values of c_4 are higher than usual. The only months in which the value of α_4 departs by more than 60° (equivalent to one hour in time) from the normal value are July and November ; from February to May, inclusive, the departure does not exceed 10°.

Harmonic Coefficients of the Diurnal Inequality of Atmospheric Pressure—Eskdalemuir, Longitude 3° 12′ W.

Values of c_n, α_n in the series $\Sigma c_n \sin(15nt° + \alpha_n)$, t being Local Mean Time reckoned in hours from midnight.

NOTE.—*Winter* comprises the four months January, February, November, December.
Equinox the months March, April, September, October.
Summer the months May to August.

Temperature.—The mean temperature, 280·29a. (45°·1F.), for the year was the highest since 1921, and was 0·4a. (0°·7F.) above the average. Departures of the mean values for individual months from the corresponding normals range from +1·5a. (2°·7F.) in February to −2·2a. (4°·0F.) in October. The mean daily temperature was above normal on nearly all days from February 19 to March 17, from March 27 to April 15, from June 29 to September 19 ; and below normal from May 3 to May 23, and from October 10 to November 3. November 1 was the day with lowest mean temperature, 270·6a. (27°·6F.), and also the lowest instantaneous value, 262·6a. (13°·3F.). The highest temperature of the year was 300·0a. (80°·6F.), on July 14, but the maximum recorded on the previous day was only 0·1a. (0°·2F.) less. The highest daily mean, 294·0a. (69°·8F.), occurred on July 13. Noticeably large range of temperature was experienced in September and in October, the minimum temperature in both months and the maximum in September constituting a "record" for the respective months. The September maximum, 295·9a. (73°·3F.), and highest daily mean value, 290·4a. (63°·3F.), occurred on the 18th, when most of the country was under the influence of a southerly air current forming part of the circulation of a large continental anticyclone; while the minimum value, 269·3a. (25°·3F.), and the lowest daily mean, 276·2a. (37°·7F.), occurred on the 26th, during the régime of north-westerly air supply in the rear of a depression which passed over northern Scotland on the 25th. In October the extreme values, 294·0a. (69°·8F.) on the 4th and 264·7a. (17°·1F.) on the 31st at midnight, were recorded in anticyclonic conditions. On the former date a large anticyclone was centred over northern England, while on the latter date there was an anticyclone over Ireland. For some days before October 31 the air over Scotland had been of "polar" origin. October 31 was practically cloudless and the night radiation cooling culminated in the lowest temperature of the year at 3h 12m on November 1. On 21 days of the year the mean daily temperature did not exceed 273·0a. (32·0F.), and there were 103 days on which the minimum temperature recorded did not exceed this value.

The mean absolute daily range varied from 4·7a. (8°·5F.) in January to 9·4a. (16°·9F.) in May, the mean for the year being 7·3a. (13°·1F.). In nine months the mean absolute daily range was less than the corresponding normal value; the value for February was only 88 per cent. of the normal, but this was the only month in which departure from normal exceeded five per cent. The greatest and least daily ranges were 17·2a. (31°·0F.) and 0·9a. (1°·6F.) on April 13 and January 15, respectively.

In the months from April to August and in October and December the range of the mean diurnal inequality of temperature is greater than that of the corresponding inequality computed for the years 1911-23, but only in October and December is the range more than 10 per cent. in excess of the normal. The inequality range for February is 23 per cent. below the normal. The hours of occurrence of the maximum and minimum values in the inequality show no special features, except that in February the minimum is at 23h.

Humidity.—As is mentioned in the General Introduction, owing to a change in the hygrometric tables employed the results for 1926 are not strictly comparable with those of previous years. In comparison with the average values for 1911-25 the mean relative humidity was high in January, February, April, November, and low in May, October, December; the extreme departures from average values being an excess of 5 in February and a deficiency of 4 in December. The greatest and least mean daily values of relative humidity were 98·5 and 61·1, on February 24 and May 17, respectively. The smallest hourly value, 36, occurred on the latter day. In the mean diurnal inequalities of relative humidity for individual months the minimum value occurs at 13h in February, at 12h in November, and at 14h or 15h in the other months. There is more scatter in the time of the maximum value; it occurs at 21h in February and in the early morning (2h to 8h) in the other months. The mean vapour pressure for the year was somewhat higher than that of the four preceding years.

Rainfall.—The total amount for the year, viz., 1713·8 mm. (67·47 in.), is surpassed only by the amounts recorded in 1916 and 1923. January, with 239·5 mm. (9·43 in.), was the wettest month, and December, with 51·3 mm. (2·02 in.), the driest. In no previous year was the December total as small as in 1926. March and May were the only other months in which the total rainfall was below average. The November total was 52 per cent., and the January, February, June, July totals were from 39 to 46 per cent. in excess of the corresponding average values. Precipitation fell at a rate of not less than 0·1 mm. per hour for a total period of 1,303 hours, the monthly duration being greatest, 184·5 hours, in February, and least, 60·3 hours, in December. The average rate of fall varied between rather more than 2 mm. per hour in August and September, and about 0·85 mm. per hour in March and December.

Precipitation amounting to 0·2 mm. or more was recorded on 235 days, while there were 21 days on which the amount exceeded 20 mm. The greatest amount on a calendar day was 49·9 mm. (1·96 in.), on November 4; while the largest amounts tabulated for a single hour were 11·2 and 10·0 mm. on August 20 and October 9, respectively. No rain was recorded between 20h and 21h on any day in December.

Snow or sleet fell on 39 days, but on no day from May 16 to October 21, inclusive. Observations of "snow lying" at 7h were made on 16 days, 10 of which were in January.

Sunshine.—The year's total duration of bright sunshine, 1150·3 hours, represents 25·7 per cent. of the theoretically "possible" duration; whereas the average percentage of "possible" for the years 1911-26 is 27·1. Compared with the average duration the greatest deficiency is in February, April and November, the total duration for these months being only from 60 to 65 per cent. of the average values. The April total, 85·5 hours, is the lowest registered in that month during the years 1909-26. Apart from 0·2 hour on February 8 no sunshine was recorded from the 2nd to the 10th, inclusive, of that month. The totals for August, October and December are from 20 to 30 per cent. in excess of the average values. The highest daily amounts were 13·3 hours on June 3 and 13·2 hours on August 1, but the highest values of the percentage of "possible" sunshine were 91·1 on October 31 and 90·3 on the day before. There were 92 days on which no sunshine was recorded. This number is slightly less than the average. Sixty of these sunless days occurred in the first two and last two months of the year. Days on which 50 per cent. or more of the "possible" sunshine was recorded numbered 70, 10 of these occurring in each of the months May and October.

Wind.—The mean speed for the year, 4·9 metres per second (11 miles per hour) was slightly below the average for the years 1911-26. The mean speed in March was 0·9 metres per second above, and the mean speeds in April and November were, respectively, 0·9 and 0·7 metres per second below the corresponding average. In only one April, viz., in 1922, has the mean speed been less than the value, 4·3 metres per second, in 1926. November 5 was the day with the highest average speed, viz., 15·4 metres per second (34·5 miles per hour). The highest hourly wind speed of the year, 20·6 metres per second (46·1 miles per hour) occurred on the same day, during ten hours of gale from south-south-west. The highest instantaneous speed reached on this day was 31 metres per second, but the west-north-westerly gale of October 9 was responsible for the highest gust of the year, 32 metres per second. There were, during the year, 27 hours of wind of gale force (mean speed greater than 17·1 metres per second). In only three former years was the number of hours of gale smaller than in 1926. On 21 days the mean speed was less than 1·6 metres per second, there being four such days in October and six in November. In the interval from November 23d 17h to November 25d 18h the mean hourly speed exceeded 0·6 metres per second in only one hour.

Grass Minimum Temperature.—In comparison with the values for the years 1917-25 the mean values for February, March and April are rather high, while the value for October is low. November and December are the only months for which the mean values are definitely below the freezing point of water. 260·9a. (10°·3F.), during the night of October 31-November 1, was the lowest value recorded in the year. From October 15 to November 10 there were only three mornings on which the grass minimum reading exceeded 273·0a. (32°·0F.). There were 104 occasions of ground frost (*i.e.*, grass minimum temperature not greater than 272·1a., or 30°·4F.), but there was no occasion of ground frost between June 3 and September 25.

Cloud and Weather.—(A) The mean amount of cloud for the year, 7·7, is slightly greater than that for 1925, but less than the mean amounts for 1922-24. February was the most, and October the least cloudy month, the mean amounts being 8·9 and 6·6. The highest mean amount for an observational hour is 9·1 at 9h in February, while the lowest is 5·7 at 21h in April and October. For the year as a whole the mean amount of cloud was greatest, 8·1, at 13h and least, 7·1 at 21h. Considering the months individually, it will be seen that the greatest mean amount occurred at 7h in November, at 9h in January, February, December, and at either 13h or 15h in the other months. Similarly, the hour of least average cloud amount was 7h in June, 18h in January and December, and 21h in the other months. The most noteworthy approximately cloudless interval of the year was that from 21h on October 29 to 21h on October 31, the only cloud observed at the standard times being one-tenth of strato-cumulus at 18h on October 30 and traces of cumulus in the afternoon of October 31. As is mentioned above, more than 90 per cent. of the "possible" sunshine was recorded on October 30 and 31, while the night of the latter day was the coldest of the year.

(B) Thunder was heard on 16 days, one of which was in a winter month. In 1925 there were 17 days with thunder, but in no one of the years 1919 to 1924 did the number of such days exceed nine. There were observations of solar halo on 11 days, of lunar halo on 4 days, and of aurora or auroral glow on 7 days. The aurora of the night of October 15-16 extended well south of the zenith and was one of the most remarkable witnessed at Eskdalemuir for several years.

(C) The numbers of occasions on which the range of visibility was estimated to be (1) not greater than 500 metres (550 yards), corresponding with the entries X to E, and (2) at least 20 kilometres ($12\frac{1}{2}$ miles), corresponding with the entries k, l, m, are summarized below. The limitations to which the estimates of visibility are subject are mentioned on p. 129. It is to be noted that the group (1) above consists of the occasions which are held to merit the description as "fog, moderate, thick, or dense," while the entries k, l, m, denote "very good or excellent visibility." Fog was most frequent in January and February, but was entirely absent in May. Occasions of very good and excellent visibility were most numerous from May to October, inclusive. The estimates l and m, *i.e.*, visibility at least 30 kilometres ($18\frac{2}{3}$ miles), occurred most frequently in March and May, the number of occasions being, respectively, 21 and 24. There were 14 occasions on which the visibility was estimated to be 50 kilometres (31 miles) or more. The majority of these occasions were at 15h or 18h, and all but two were associated with winds from west-south-west through north to north-east. In eight months the frequency of occurrence of very good and excellent visibility was greatest at 15h.

ATMOSPHERIC ELECTRICITY.

Notes on the Instruments.

Autographic records of atmospheric electrical potential gradient were obtained by means of an electrograph of the Kelvin water-dropper type, the potential at the water-jet being registered by a Dolezalek quadrant electrometer. In all essential details the electrograph arrangements, the method of making scale and insulation tests and the method of reducing the autographic curve readings to potential gradient in the open were as described in the *Observatories' Year Book*, 1922, pp. 75–76.

The scale value of the photographic record obtained by means of the Dolezalek electrometer remained at about 3·1 volts per millimetre during 1926. The number of determinations of the reduction factor (*i.e.*, the ratio of the potential at one metre above the ground in the open to the potential at the water-jet) varied from six in January, February and September to twelve in June and October, each determination being based on about fifteen or more readings (at intervals of one minute) of the potential in the open. The values of the monthly reduction factor finally adopted for 1926 were obtained by a smoothing process, the adopted value for a given month being $\frac{(a + 2b + c)}{4}$, where a, b, c are the unsmoothed monthly mean factors for the three successive months centred in the given month. The final values, which are given in Table 260, range from 6·27 in January to 5·96 in July. The mean of the twelve monthly reduction factors is 6·14 for 1926, as compared with 6·31 for 1925.

All determinations of scale value and reduction factor were obtained with a particular Wulf quartz-thread electrometer. Between November, 1926, and April, 1927, a number of calibrations of this instrument were carried out, employing a potentiometer and a Weston standard cell. The finally adopted calibration, which was in close agreement with that used in 1925, was employed in reducing the results for 1926.

IDENTIFICATION NUMBERS OF INSTRUMENTS USED IN 1926.

Wulf bifilar electrometer 3040

Notes on the Tables and Results.

As far as possible an electrical character figure is assigned to each day and values of potential gradient are assigned for 3h, 9h, 15h and 21h G.M.T. on all days, while values for all hours are assigned on days classified as 0*a*, 1*a* or 2*a*. The character figures are given in Table 263, the significance of these symbols being as follows :—

0, denotes a day during which from midnight to midnight no negative potential was recorded.

1, denotes one or more excursions of limited duration to the negative side of the scale during the same period.

2, denotes negative potential extending in the aggregate over three hours or more during the same period.

a, denotes that within the 25 periods of 60 minutes for which an estimate of the mean potential gradient has to be made in the process of tabulation there was in no case a range of potential gradient in the open exceeding 1,000 volts.

b, denotes that, during the same period, a range of 1,000 volts or more was reached in one hour at least but in fewer than six hours.

c, denotes that, during the same period, a range of 1,000 volts or more was reached in at least six hours.

Table 260 contains the values of electrical potential gradient at 3h, 9h, 15h and 21h G.M.T. daily, the value for a given hour representing the mean for the period of 60 minutes centring at that hour. Blanks indicate that the trace was in some way defective. The reduction factors used in converting the potential at the water-jet to potential gradient, in volts per metre, in the open are also given.

In Table 261 are given, for 0*a* days, (1) the mean diurnal inequalities for the months, seasons and year, (2) particulars of the number of days and of the non-cyclic changes and (3) the corresponding mean values of potential gradient. The inequalities or the mean values for the year and seasons are the means of the inequalities or means, respectively, for the appropriate months.

Corresponding data for 1*a* and 2*a* days combined appear in Table 262.

It should be noted that, in these tables, *Winter* denotes the four months January, February, November, December ; *Equinox* the four months March, April, September, October ; and *Summer* the four months May to August.

Contrary to the practice followed in some earlier years[1] the mean values of potential gradient given in Table 260 are of two kinds, viz., (*a*) the means of all the positive values of potential in the column and (*b*) the algebraic mean derived from all days on which all four hours were represented. The mean values for the month, as derived from the (*a*) and (*b*) values respectively, are shown in the last line, and the means for the year are given at the foot of the December table. It is to be expected that the mean derived from the values at 3h, 9h, 15h and 21h, on a sufficiently large number of days, will approximate closely to the mean value derived from all hourly values of all the days.

The (*a*) mean exceeds the (*b*) mean in all months of 1926, and is exceeded by the mean value of 0*a* days in all months with the exception of June and August. The 0*a* mean values in those months are, however, only slightly less than the (*a*) means. January, April and October are the only months for which the (*a*) or (*b*) mean, or the mean on 0*a* days, is greater than the corresponding quantity in 1925. Annual mean values for recent years, derived by giving equal weight to the twelve monthly means, of the (*a*) and the (*b*) means and of the means for 0*a* days are as follows :—

	0*a*	(*a*)	(*b*)
	v/m.	v/m.	v/m.
1922	257	225	182
1923	278	235	159
1924	236	214	157
1925	284	243	209
1926	249	201	177

The percentage decrease in annual mean value from 1925 to 1926 is 12, 17, 15 for the 0*a*, (*a*), and (*b*) means, respectively. It may be noted that the mean reduction factor for 1926 is only three per cent. less than that for 1925. The annual mean value on 0*a* days is 11 v/m less than the average value, 260 v/m, for the years 1913-25. In all four summer months of 1926 the mean value on 0*a* days is below average, the mean for the summer season being about 15 per cent. below the average. The highest value of the (*a*) mean and of the mean on 0*a* days occurred in November. In that month there were only three 0*a* days, viz., 3rd, 7th, 24th, the values of the mean potential gradient being, respectively, 515, 326, 318 v/m. High potential occurred in association with wet fog in the morning of November 3.

Other noteworthy occasions of high potential gradient were as follows :—

(i) January 12d 6h to 23h. The mean potential gradient during this interval was 780 v/m, and was associated with slight mist and, later, fog.

(ii) On the night of March 4th a high wind with much drifting of snow was accompanied by several hours of high potential gradient. A potential of more than 1,200 v/m was reached at times.

---

[1] *i.e.*, prior to 1923.

(iii) From July 11d 19h to 12d 9h during a spell of wet fog the potential gradient remained fairly steady and high, the highest hourly value during this period being 570 v/m at 8h on the 12th.

(iv) August 4d 21h to 5d 7h 30m. A period of high potential, during wet fog, in which a potential gradient of more than 800 v/m was recorded at times.

(v) December 6d 11h to 23h. Thirteen hours of high potential gradient, the mean value of which for the interval was 640 v/m. The early part of this interval was calm ; wet fog occurred in the last few hours.

The following were the more noteworthy occasions of continuous negative potential gradient :—

(i) January 23d 2h 37m to 11h 28m, during part of which the potential was below −1,400 v/m.

(ii) January 25d 2h 7m to 9h 52m, in three hours of which the potential reached values below −1,300 v/m.

(iii) February 5d 14h 10m to 22h 18m. For 1h 20m of this period the potential gradient exceeded the limits of registration, and was considerably below −1,500 v/m.

(iv) June 11d 10h 40m to 11d 16h 40m. These six hours of continuous negative potential gradient were part of a very disturbed period extending from June 10d 3h to June 11d 20h.

(v) November 2d 15h 10m to 2d 23h 25m, during which period the range was very small, the lowest potential recorded in the interval being −470 v/m.

(vi) November 4d 21h 8m to 5d 5h 10m, for four hours of which the potential was less than −1,500 v/m.

In all the above cases, with the exception of (v), continuous moderate or heavy rain was falling. During (v), intermittent sleet was experienced.

On the following occasions long periods of negative potential gradient were broken by short excursions to the positive side :—

(i) January 29d 1h 0m to 10h 46m. During this period the potential attained a very small positive value for only five minutes. At times during the remainder of the period very large negative potentials were reached, the trace being off the sheet continuously from 5h 40m to 10h 10m. Rain was falling throughout the interval.

(ii) September 20d 1h 10m to 11h 20m. During a heavy thunderstorm, with much lightning, after about one hour of high positive potential, there followed a period of nearly four hours of continuous negative potential. A short excursion to high positive potential was then followed by more than four hours of continuous negative potential.

(iii) November 1d 20h 18m to 2d 9h 25m. During rain and sleet the potential gradient was negative for over seven hours, except for momentary excursions to the positive. Then followed two short periods of positive potential, succeeded by over four hours of negative potential. The limits of registration on the negative side (−1,600 v/m) was exceeded in the aggregate for over five hours.

(iv) November 18d 15h 54m to 19d 3h 23m, during which spells of six and four hours continuous negative potential were separated by two short excursions to the positive. Rain was falling throughout, and for a large part of the first spell potential was below −1,400 v/m.

During the interval March 18d 10h 0m to 14h 30m an interesting series of pulses of negative potential was recorded during passing showers of rain. The lengths of the successive intervals of negative potential were 27, 27, 29, 25, 26, and 22 minutes. The greatest negative potential was reached in the culmination of the penultimate interval, the value being −634 v/m. In some of the showers with which these pulses of negative potential were associated the rain recorded by the Beckley gauge was almost imperceptible. Each occasion was associated with a small wind squall, involving change in wind direction, but the sequence of wind changes recorded is not (at least superficially) the same in each case.

Although there are considerable irregularities in the mean diurnal inequalities of potential gradient on 0*a* days for individual months, the mean inequalities for the seasons resemble fairly closely the normals for 1913-23. In winter the principal minimum occurs in the early morning, and the principal maximum in the evening. The tendency towards a secondary maximum in the forenoon is more noticeable than usual in this season. The effect of the high ranges of the inequalities for January, November and December is manifest in the large range of the winter inequality. In the mean diurnal inequality for equinox the chief minimum is at 12h and the chief maximum at 20h to 22h. There is also in this season a well-marked secondary maximum at from 5h to 8h. In the summer inequality the minimum occurs at 15h, which is somewhat later than usual ; and the maximum is at 1h or 2h, whereas in the normal inequality for this season the maximum occurs at 21h to 22h.

TERRESTRIAL MAGNETISM.

Notes on the Instruments.[1]

The magnetographs in use are situated in the east chamber of the underground magnet house and are arranged so as to record changes of the three geographical components of terrestrial magnetic force, viz., the north component, N (or + X), west component, W (or — Y), and the vertically downward component, V (or + Z).

The diurnal range of temperature in the east chamber of the magnet house is normally negligible. Temperature is ascertained daily at 9h 30m by the thermometers within the instrument cases. The daily values appear in Tables 267, 271, etc. ; the monthly means of the readings so obtained during 1926, together with the mean values for the years 1911–25, were as follow :—

EXCESS OF MEAN TEMPERATURE ABOVE 280a.

Month.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Mean 1926	3·0	2·5	2·5	2·7	3·1	4·1	5·1	6·2	6·9	6·6	5·6	4·5
Mean 1911–25	3·6	3·1	2·7	2·4	2·8	3·6	4·6	5·7	6·3	6·2	5·6	4·6

The annual range of temperature during 1926 was 4°·5 C., the mean range for the previous fourteen years being 4°·2 C.

[1] For more detailed accounts of the magnetographs, absolute instruments, and normal methods of procedure, see *The Observatories' Year Book*, 1922, pp. 77 *et seq.*

The north and west component instruments are of the bifilar type, by Adie. In each of these instruments the torsion of a bifilar suspension, of fine tungsten-steel wire, is utilised to bring the magnet into an azimuth approximately perpendicular to the direction of the component of which the changes are recorded. In December, 1926, determinations of the azimuth of the magnetograph magnets were carried out, by comparing the deflections produced by an auxiliary magnet with its axis (*a*) true north-south, or east-west and (*b*) inclined at a known small angle to those azimuths. It was found that the departures of the azimuths of the magnetograph magnets from the normal azimuths were not more than 0°·5. No adjustment was made to these instruments in 1926.

The instrument for the vertical component is a multiple magnet balance designed by the late Professor W. Watson, F.R.S. This instrument is very sensitive to mechanical disturbance. Displacements of the magnet system, and discontinuities in the record, due to disturbance occasioned by structural alterations to portions of the magnet house, by the lifting and re-setting of the magnet, or by scale test operations, occurred on January 21, 22, 23, 24, 29, 30, February 1, 2, March 17, 18, 19. The only adjustments to the instrument consisted of lifting and re-setting the magnet system on January 24, March 17, 19.

The constants of the magnetographs were as follow :—

	North.	West.	Vertical.
Time scale .. .. 1 hour =	15·5 mm.	15·5 mm.	15·5 mm.
Time marks	Every two hours, beginning at exact hour.		
Error of time mark	Not more than ± 1 min.		
Period of vibration, seconds	13·9	9·9	7·4
Logarithmic decrement[1]	·365	·569	—
Angular equivalent of 1 mm. on paper, radians ..	·00032	·00032	·0003
Twist of bifilar suspension	60°	30°	—
Ratio $\frac{\text{length of bifilar suspension}}{\text{mean breadth of suspension}}$	66	100	—
Temperature coefficient, per 1° C.	−9 γ	−2 γ	+26 γ
Direction of marked pole	West.	North.	—
Azimuth of magnet	270°	0°	346°

[1]Log. decr. = $\mathrm{Log}_e a_n - \log_e a_{n+1}$; where a_n, a_{n+1} are the amplitudes of two successive swings on the same side of the zero position.

The scale values of the magnetographs were determined at intervals of two weeks. In the following table are given the scale values, obtained by overlapping means, which were employed in reducing the curve readings.

SCALE VALUES OF THE MAGNETOGRAPHS (γ per mm. on the paper).

Month.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
North Instrument..	4·97	4·95	4·95	4·95	4·95	4·94	4·93	4·93	4·94	4·94	4·92	4·91
West Instrument ..	6·62	6·62	6·62	6·61	6·61	6·62	6·61	6·61	6·61	6·62	6·61	6·62
Vertical Instrument	[1] 4·43 [2] 4·31	[3] 4·28 [4] 4·14	[5] 4·14 [6] 4·29	4·29	4·32	[7] 4·32 [8] 4·42	4·47	4·53	4·56	4·49	4·36	4·30

[1] to 24d 10 hr ; [2] from 24d 11h ; [3] to 24d ; [4] from 25d ; [5] to 17d 10h ; [6] from 17d 17h ; [7] to 10d ; [8] from 24d.

The scale values for the vertical instrument for the days June 11 to June 23 were obtained by interpolating smoothly between the values 4·32 and 4·42.

Absolute observations of horizontal force, declination, and inclination were taken, usually twice weekly, in the east magnetic hut. Declination and horizontal intensity were determined by means of the Kew pattern unifilar magnetometer placed on Pier No. 5. In the deflection experiment of the horizontal intensiy, determination observations were made for three distances of the collimator magnet, viz., 25, 30, 35 cm.

As in 1924 and 1925, the procedure in respect of the P and Q correction, $\log_{10}(1+P/25^2+Q/25^4)$, which is used in the reduction of the horizontal intensity observations, differed from that which had been followed from the latter part of 1913 until 1923. Throughout the period named the value of the correction adopted for a given month was the mean derived from the observations obtained during the seven months including the given month as fourth of the seven. The monthly values so derived show considerable fluctuations, and it is improbable that P and Q actually varied to the extent implied. It was decided to use throughout 1926 a value based on the observations during the years 1917–26. From the values of m/H for the three deflection distances, during each of these years, a mean value of $\log_{10}(1+P/25^2+Q/25^4)$ was computed and the mean of the ten values so obtained was used in reducing the 1926 observations. The values of P, Q, and $\log_{10}(1+P/25^2+Q/25^4)$ are as follows :—

Year.	P.	Q.	$\log_{10}(1+P/25^2+Q/25^4)$.
1917	+6·862	+418·9	·00520
1918	+7·604	+ 68·6	·00533
1919	+9·126	−603·5	·00563
1920	+8·224	−216·6	·00544
1921	+7·978	+ 25·3	·00554
1922	+6·607	+513·1	·00513
1923	+6·371	+614·3	·00508
1924	+7·899	−128·6	·00531
1925	+8·214	−261·7	·00538
1926	+9·675	−938·4	·00564

The mean value of $\log_{10}(1 + P/25^2 + Q/25^4)$ for 1917–25 is ·00534 ; for 1917–26, is ·00537. A variation of ·00020 in the value of the logarithm corresponds with a variation of about 4 γ in the derived value of H.

Determinations of inclination (dip) were made with the Schulze inductor—placed on Pier No. 6—until April 12, on which date the instrument was sent to London in order to be forwarded to the maker for re-conditioning of the scale of the vertical circle and for general overhaul. For various reasons the period of absence of the inductor was unduly prolonged and the instrument was not again available for use at Eskdalemuir until March, 1927. In the absence of the inductor the dip circle was used for observations of inclination. From a series of comparison observations made in March and April, 1926, it was found that the average excess of the value of inclination obtained by dip circle observations over that obtained by inductor observations was +0′·47. A further series of comparison observations made in March and April, 1927, *i.e.*, after the return of the inductor, showed that the average difference between the values of inclination obtained by the two instruments was then negligible. Messrs. Schulze state that a cross-connexion was discovered in one coil of the inductor. It is not known when this defect originated. It appears improbable that, for a given value of inclination, the same observed value was given by the inductor immediately before and after absence from Eskdalemuir. There is similar uncertainty with regard to the dip circle observations, for the behaviour of the two dip needles was not constant throughout the interval April, 1926, to April, 1927, and it is unlikely that the observed values of inclination at the beginning and end of this interval are strictly comparable. The difference of 0′·47, found between the inductor and dip circle in March-April, 1926, entails a difference of 19γ in the value of vertical force derived from the two sets of inclination values. However, the run of the two corresponding sets of base line values of the vertical force magnetograph suggests that in mid-April, 1926, the value of vertical force derived from dip circle values of inclination exceeded that derived from inductor values by only $+15\gamma$. The final values of vertical force between April 13 and December 31, 1926, have been obtained by deducting from the vertical force values derived directly from dip circle values of inclination amounts diminishing from 15γ in April to 4γ in December.

In November, 1926, the Schulze inductor was compared with the standard inclination instrument at Potsdam Observatory. Dr. Venske reports that the inclination value given by the Eskdalemuir instrument was at that time $0'\cdot13$ greater than that given by the Potsdam standard.

The base line values of the magnetograph records are deduced from the results of the absolute observations, any of the latter obtained during times of considerable disturbance being excluded. The base line values finally adopted are obtained from a curve drawn smoothly through points given by the deduced values, due allowance being made for discontinuities in the records.

The results of the absolute determinations of D, I and H are summarized in the subjoined table, and the values of m, the moment of collimator magnet 60a, are also given. For each set of absolute observations are shown the deduced base line values of N, W, and V and, in brackets, the adopted base line values. Thus, the entry 15823 (18) signifies :—deduced base line value 15823, adopted base line value 15818. The adopted values were obtained as described in the foregoing, and therefore the base line values corresponding to dates between those given in the table may be obtained by interpolation, excepting for V on January 21, 22, 23, 24, 29, 30, February 1, 2, March 17, 18, 19, 20, on which dates special allowance had to be made for trace discontinuities. Details of the base line values assigned to all of these days do not appear in the table. After April 12 the deduced base line values for V are those derived from the dip circle observations of inclination, while the corresponding adopted base line values are less than those obtained by the usual smoothing process by amounts which vary from 15γ in April to 4γ in December.

Absolute Determinations of D, I and H, and Base Line Values of N, W, and V.

Eskdalemuir: **1926.**

The hourly readings are obtained from the magnetograms, standardized as described in the foregoing, by means of a ruled glass scale. The reading for any given hour G.M.T. is that ordinate estimated to be the mean reading for 60-minutes centring at the given hour. The product of this ordinate and the scale value is added to the adopted base line value, and the sum so obtained is the hourly value printed in the tables.

IDENTIFICATION NUMBERS OF INSTRUMENTS IN USE IN 1926.

Unifilar Magnetometer, Kew pattern.. .. .. (with collimator magnet, 60a, and mirror magnet, 60c).	Elliott, No. 60.
Dip Inductor	Schulze, No. 103.
Dip Circle .. .. {with needles 74 (1) and 74 (2)}.	Dover, No. 74.

Notes on Tables.

The hourly values of N, W, and V, obtained as described above, appear in three of the four monthly tables. The mean value for the day is computed according to the expression

$$x = \{\tfrac{1}{2}(x_0 + x_{24}) + x_1 + x_2 + \dots\dots\dots\dots + x_{23}\}/24.$$

The letters "Q" and "D" denote the five quiet and the five most disturbed days as selected at De Bilt.

In the fourth table for each month are given :—

(*a*) the values and times of the daily maximum and minimum and the values of the absolute daily range for each of the components N, W and V.

(*b*) the value of ΣR^2[1] for each day. ΣR^2 is written for $R_N^2 + R_W^2 + R_V^2$ where R_N, R_W, R_V denote the absolute ranges for a calendar day of the north, west and vertical components.

(*c*) the "characteristic ratio," ρ, which is the ratio of the value of ΣR^2 for a given day to the mean monthly value of ΣR^2. This ratio is an index of the degree of disturbance or activity on a given day relatively to the other days of the same month.

(*d*) the daily magnetic character figures, assigned according to the international scheme wherein "0," "1," "2," respectively, denote quiet, moderately disturbed and highly disturbed conditions.

(*e*) the daily values of temperature in the underground magnetograph chamber.

---

[1] See also p. 148.

Mean diurnal inequalities of the components N, W, V, H, D, and I on " all " days and on international quiet and disturbed days are given, for the months, seasons and year, in Tables 312 to 329. In calculating diurnal inequalities the non-cyclic change has been eliminated on the assumption that its time-rate is linear. Inequality values are first calculated to 0·01 γ and then rounded off to 0·1 γ. The inequalities of H, D, and I have been computed from those of N, W, and V by means of the formulae :

$$\delta D = \frac{180 \times 60}{\pi} \left(\frac{\delta W \cos D - \delta N \sin D}{H} \right)$$

$$\delta H = \delta N \cos D + \delta W \sin D$$

$$\delta I = \frac{180 \times 60}{\pi} \cos I \left(\frac{\delta V \cos I - \delta H \sin I}{H} \right)$$

in which δD and δI are expressed in minutes of arc, and where H, D, and I for any given month are the respective mean values for that month as published in Table 333. The values of the range of the mean diurnal inequalities of the several elements on the three different types of day are brought together in Table 330, and the values of the non-cyclic change of N, W, and V are given in Table 331.

The results of harmonic analysis of the mean diurnal inequalities of N, W, and V for the months, seasons[1] and year are to be found in Tables 334 and 335, in which are given the values of a_n, b_n, c_n, and α_n, in the two equivalent series $\Sigma\,(a_n \cos 15nt^\circ + b_n \sin 15nt^\circ)$ and $\Sigma\, c_n \sin (15nt^\circ + \alpha_n)$. In the former series t is reckoned in hours from midnight G.M.T., whilst the published values of α_n refer to Local Mean Time. The values of the harmonic coefficients have been computed from the unrounded values of the inequalities and have been corrected, where necessary, on account of the fact that the hourly values are not instantaneous values but are mean values. The factors by which the coefficients have to be multiplied (*vide* Report of the British Association, 1883, p. 98) are 1·00286 for a_1, b_1, c_1 ; 1·01152 for a_2, b_2, c_2 ; 1·02617 for a_3, b_3, c_3 ; and 1·04720 for a_4, b_4, c_4. Finally, the values were rounded off to 0·1 γ.

The mean values of the squares of the absolute daily ranges are summarized in Table 332.

In Table 333 appear for the months and year the mean values of N, W, V, D, I, H and Total Force, T. The means of the four latter elements are derived from the corresponding mean values of N, W and V, which are the means of hourly values on " all " days in the month or year. Tables 336 and 337 contain mean values of the magnetic elements for 1926 and recent years at a number of observatories.

Review of Results of Magnetic Observations.

Mean and Extreme Values of the Magnetic Elements, 1926.—The mean values are given below in Table I along with the corresponding values for the previous year. The values of N, W, and V have been computed from the hourly values derived from the autographic records of " all " days, standardized by means of the absolute observations ; those of H, D, I, and T have been deduced from the values of N, W, and V.

---

[1] The seasons are defined for this purpose as follows:—*Winter*, January, February, November, December ; *Equinox*, March, April, September, October ; *Summer*, May, June, July, August.

TABLE I.

Year.	H.	D. (West).	I.	N.	W.	V.	T.
	γ	° ′	° ′	γ	γ	γ	γ
1925	16665	15 48·4	69 39·3	16035	4539	44943	47933
1926	16648	15 35·3	69 40·3	16035	4474	44939	47923

The increased rate of decrease in westerly declination which became apparent in 1921 was fully maintained, the decrease from 1925 to 1926 being the largest change, from one year to the next, recorded at Eskdalemuir. Declination has decreased since 1920 at an average annual rate of 12′·4, as compared with an average of 9′·3 between 1913 and 1920. Horizontal force continued to decrease, but rather more rapidly than in recent years. There was no change in the mean value of the north component, but the decrease of 65γ in the west component is the largest yet recorded. Inclination increased by 1′, the values for 1926 and 1921 being the largest annual values on record. Vertical and total force decreased. The values of inclination, vertical and total force are not improbably affected by the change, in April, 1926, of the standard instrument used for observations of inclination. This change is referred to in greater detail on p. 141.

Mean values derived from (*a*) international quiet days and (*b*) international disturbed days are as follow: (*a*) N, 16040 γ; W, 4476 γ; V, 44938 γ; (*b*) N, 16024 γ; W, 4470 γ; V, 44939 γ.

The differences between the mean annual values of N, W, and V, derived from "all," international quiet, and international disturbed days, are given below, together with the mean differences for the years 1915-1925. In every year of the series quoted the mean value of N and of W on quiet days exceeded the mean value on "all" and on disturbed days. For N and W the differences for 1926 approximate to those for 1918. The only other years for which either the "all" or the disturbed day mean value of V exceeded the quiet day value were 1917, 1919, 1921.

	Quiet day mean-"All" day mean.			Quiet day mean-Disturbed day mean.		
	N	W	V	N	W	V
	γ	γ	γ	γ	γ	γ
1926 ..	+4·8	+2·0	−0·7	+16·1	+5·7	−1·4
1915-1925	+2·7	+1·2	+0·7	+ 8·5	+3·3	+1·5

The resultant vector representing the average excess of the mean values on "all" days over the mean values on quiet days, for the years 1915-1925, has a magnitude of 3γ; its azimuth is 156°, measured from true north through east, and it is inclined at about 77° to the upwardly directed vertical. The vertical plane which contains this vector approximates very closely in azimuth to the vertical plane passing through Eskdalemuir and the pole (taken as 78°N, 68°W) of the axis of magnetization of the earth. (cf. S. Chapman, *On certain average characteristics of world-wide magnetic disturbance.* Lond. Proc. Roy. Soc. Series A. Vol. 115, p. 242).

The extreme values of N, W, and V recorded during 1926 are given in Table II.

TABLE II.

Component.	Maximum.			Minimum.			Absolute Annual Range.
	Value.	Date, 1926.		Value.	Date, 1926.		
	γ		d h m	γ		d h m	γ
North	>16422	Jan.	Between 26 20 52 and 26 21 10	<15604	Apr.	Between 15 7 16 and 15 7 43	> 818
West	4925	Oct.	15 19 22	< 3968	Oct.	Between 15 23 5 and 15 23 15	> 957
Vertical ...	>45284	Mar.	Between 5 17 9 and 5 18 5	<44565	Oct.	Between 15 22 17 and 16 0 45	> 719

Owing to the recording spots of light passing beyond the edges of the bromide paper during certain of the disturbances it is probable that the extremes given above depart considerably from the true values. This is especially so for N and V, and it is not unlikely that the extreme values of these two components may have occurred on dates other than those given. The recorded absolute annual range in W and in V is not exceeded by the corresponding value in any previous year, while the range in N is surpassed only by the values for 1915 and 1917.

Magnetic Character of the Year.—General agreement not having been reached yet as to the most suitable method of obtaining a numerical measure of magnetic activity, the Eskdalemuir practice of tabulating for each day the value of ΣR^2[1], *i.e.*, the sum of the squares of the absolute daily ranges of N, W and V, has been continued. The evaluation of the mean daily values of Σr^2, the sum of the squares of the hourly ranges of N, W, and V, has not been carried out for 1926, but the values of hourly ranges have been tabulated and are available for the purposes of investigation. The magnetic character figures which were assigned in accordance with the international scheme are summarized in Table III. These character figures were assigned quite independently of knowledge of the values of ΣR^2. Table III contains also the mean monthly values of ΣR^2 for "all," "0," "1," "2," international quiet (Q), and international disturbed (D) days.

In comparing the magnetic character figures assigned at a given observatory in different years it is necessary to remember that change of individual responsible for assigning the character figures is likely to be accompanied by a change of standard. At Eskdalemuir such changes in personnel occurred in 1913, 1916, 1922. Also, unless the magnetic characterization is carried out on some definite basis of measurement the possibility of fluctuation of personal judgment has to be recognised. The character figures assigned at Eskdalemuir indicate that 1926 was a much more disturbed year than 1925. The Eskdalemuir annual mean character figure has increased fairly steadily from 1923 to 1926, but the increase is much more marked than that of what may be termed the international character figure, *i.e.*, the mean derived from the estimates of all the observatories, about forty in number, which render returns to De Bilt. The values of the international mean character figures for the years 1916 to 1926 are 0·71, 0·67, 0·75, 0·73, 0·62, 0·61, 0·65, 0·48, 0·55,

[1] See p. 145.

0·56, 0·65. The Eskdalemuir mean character figures for 1925 and 1926 are conspicuously larger than the corresponding international character figures. This seems to be due, especially in 1926, to the increase in the number of " 1 " days at the expense of the number of " 0 " days. In no previous year has the number of " 0 " days, at Eskdalemuir, been as low as 90, the number in 1926. As it seems to be of interest to look further into this matter, the values of the mean international character figure have been derived (*a*) for Eskdalemuir " 0 " days and (*b*) for days on which the international figure did not exceed 0·4, *i.e.*, days to which the figure " 0 " was assigned by a clear majority of the observatories collaborating with De Bilt. Although the effects of fluctuation in the standard adopted at individual observatories may be supposed to be largely eliminated in the international character figures, it is unlikely that the international standard remains invariable from year to year. Moreover, it is possible that in the case of some observatories a modification in standard or in the method of characterization resulted from consideration of the circular issued from De Bilt in March, 1924. However, the mean international character figures, given below, suggest that the standard for a "0" day at Eskdalemuir was more severe in 1925 and 1926 than in the three previous years. From one point of view this is somewhat surprising, for it might be expected that the degree of disturbance marking the separation between "0" and "1" would be higher in disturbed than in quiet years.

Mean international character figures.

	1922.	1923.	1924.	1925.	1926.
Eskdalemuir " 0 " days ..	0·27	0·23	0·20	0·11	0·11
Days with international figure 0·4 or less ..	0·20	0·18	0·18	0·15	0·19

The character figure " 2 " was assigned to 48 days, a larger number than in any year since 1919. 41 of the 48 Eskdalemuir "2" days are included among the De Bilt selection of most disturbed days, the remaining seven days being in months in which there were more than five Eskdalemuir " 2 " days. The mean international character figure for the Eskdalemuir "2" days is 1·6. In 1926 there were 32 days on which the international figure is 1·5 or more, and on 10 of these days the international figure is 1·9 or 2·0. The number of days with international figures within the ranges stated is greater than in any of the years 1916-25.

In considering the published values of quantities, *e.g.*, ΣR^2, which are derived from the values of the absolute daily range, it should be remembered that when the limits of the photographic paper are exceeded the reading at the paper edge is taken as the extreme and, therefore, that the adopted value of the absolute daily range may be considerably less than the true value. For this reason the values of ΣR^2 for " all," " 2 " and D days in the months January to April, June, September and October, 1926, are under-statements. The effect of numerous large disturbances in 1926 is seen in the annual mean values of ΣR^2 for " all," "2," and D days. These values are greatly in excess of those in recent years; indeed, the annual mean value of ΣR^2 on " all " days has not been exceeded in any year. Fifty-six per cent. of the annual total (all days) of ΣR^2 is contributed by sixteen days, on none of which is the value of ΣR^2 less than 200,000γ^2 or the international character figure less than 1·7; while the mean value of ΣR^2 for the remaining 349 days exceeds the all day annual mean for each of the years 1922-1925. The annual mean values of ΣR^2 for Q, "0," "1," days are all greater than in 1925, the percentage increase being somewhat greater for Q than for " 0 " and " 1 " days. According to the means of the assigned character figures, January, March, April and October were the months of greatest average disturbance, while August and November were the quietest months. A consideration of the excess of the value of ΣR^2 on all and on " 1 " days over the value on Q days suggests that the degree of disturbance was greatest from January to April or May, and in September and October. It will be noticed that the values of ΣR^2 on Q and "0" days are considerably smaller in November and December than in January and February, and smaller in the autumnal equinoctial than in the vernal equinoctial months.

TABLE III.

Month.	Magnetic Character Figures. Number of "0" days.	"1" days.	"2" days.	Mean Character Figure.	Mean Value of $\Sigma R^2/100$. "All" days.	Q days.	"0" days.	"1" days.	"2" days.	D days.

It may be recalled that, speaking generally, the latter half of 1925 was characterized by a marked increase in the degree of magnetic disturbance. A very considerable degree of disturbance prevailed during the earlier months of 1926, but, apart from the large disturbances in September and October, the average activity was apparently less in the latter half of 1926. The observed sunspot relative numbers (as given by Wolfer) for the last eight months of 1925 show a marked increase as compared with the monthly numbers during the preceding two or three years. The mean sunspot numbers for the first, second, and third four-month groups of 1925 are, respectively, 19·6, 41·7, 71·7; while the mean sunspot number for 1926 is 63·9, which is very approximately the same as that for 1919, slightly in excess of that for 1916, but considerably less than the mean numbers for 1917 and 1918. The highest mean sunspot numbers in 1926 are those for January, February, June, October and December; the numbers for April and July are rather noticeably below the average for the year.

Diurnal Inequalities.—The mean diurnal inequalities for "all" days, international quiet and disturbed days, for the months, seasons and the year, are given in Tables 312–329, and the corresponding inequality ranges in Table 330. The inequalities of N, W, and V for international quiet and disturbed days are shown graphically in Plates III and IV, the representation in the latter plate being in the form of vector diagrams.

DIURNAL VARIATION IN THE COMPONENTS OF MAGNETIC FORCE ON QUIET AND DISTURBED DAYS. ESKDALEMUIR 1926. THE YEAR & THE SEASONS

(1) *Ranges.*

(*a*) All Days.—In no case is the range of the annual or seasonal mean diurnal inequality of N, W, or V less than in 1925. Cases of the range of a mean monthly diurnal inequality being less than in the corresponding month of 1925 are confined, with one exception, to the second half of the year. The range of the annual inequality of V is greater than in any previous year, while the N and W ranges are exceeded only by the 1917 and 1918 values. The ranges of the inequality of N in January, February, March, May, of W in February, and of V in January, February, March, are unsurpassed in those particular months.

(*b*) Quiet Days.—As for all days, for none of the three components N, W, and V is the range of the annual or seasonal mean diurnal inequality less than in the previous year. In the months January to April the ranges are without exception greater than in the previous year. September is the only month in which the ranges for all three components are less than in 1925. The range of the annual mean diurnal inequality is exceeded only by the corresponding value in one or more of the years 1916 to 1919, while the N and W ranges for winter are exceeded only by the 1917 values. The values of the range of the inequality of N in February and November, of W in March and November, and of V in January are the largest on record for those months. It is somewhat remarkable that the V range in November is the smallest for that month.

(*c*) Disturbed Days.—In all three components the range of the mean diurnal inequality for the year and for equinox is greater than in any other year since 1915, the earliest year for which disturbed day inequalities are available. The highest annual ranges of the last sunspot cycle occurred in 1919, two years after the last sunspot maximum year. The annual ranges for 1926 expressed as percentages of those for 1919 are N, 110 ; W, 114 ; V, 104. The inequality ranges of N in January, February, April and October, of W in January, February, April, June and October, and of V in January, February, March, April, September and October are greater than the corresponding quantities in previous years. In eight months the range of the mean diurnal inequality of H exceeds 100γ, a value which has not been exceeded in more than four months in any one of the previous eleven years.

(2) *Harmonic Coefficients.*

In general, the tendency is for the amplitudes of the 24- and 12-hour terms for the year and seasons for all and quiet days to be less than the corresponding values in one or more of the years 1916-1919. The most prominent exceptions are the winter and equinox values of c_1 for V on quiet days, these values being less than the corresponding quantities in the majority of the preceding ten years. The all day winter values of c_2 for N and V, the equinox values of c_1 and c_2 for V, and the winter quiet day value of c_2 for N, are the greatest of their kind for the years 1916-1926. The phase of the 24-hour term for N and for V for all days, for the year, winter, and equinox, is accelerated compared with most former years. In respect of the harmonic coefficients for disturbed days, for the year, winter, and equinox, 1926 occupies a more outstanding position in comparison with former years. The values of c_2 for N for the year and winter, for W and V for the year and equinox, of c_2 for N for winter and equinox, for W for equinox, and for V for the year, winter and equinox are unsurpassed during the years 1915-1926. For the year, winter, and equinox the (disturbed day) values of α_1 for N are greater, while the values of α_1 and α_2 for W are less, than in previous years; the acceleration of the phase of the principal term for N being much more pronounced than the retardation of the phase of that term for W. In the case of V the increased amplitude of the 24- and 12-hour terms, for disturbed days, is not accompanied by any marked phase change relative to former years.

Daily Range.—The values of mean absolute daily range for the months and seasons of the year, together with the corresponding means for 1915–25 are given in Table IV; the ranges are also expressed as percentages of the mean absolute daily range for the year.

Owing to the limits of photographic registration being exceeded on certain disturbed days the absolute daily range values given in the above table for N and V in the months January to April, for V in June and October, and for N, W, and V in October are less than the true values. The mean values for the year and seasons have been derived from the monthly mean values given. In most months the mean absolute daily range exceeds the corresponding value for 1925, August, November, and December being the only months in which the mean range of each component is smaller than the 1925 value. The values of the mean range in N, W, and V in January and February, and in N in April are the largest on record on those months. The mean range for the year, for each component, is exceeded, but not considerably, only by the values for 1918 and 1919. The August, November and December values of the range in each component and the July range in N are the only cases in which the 1926 value is less than the average for the years 1915-1925. Expressed as percentages of the mean values for 1915-1925 the 1926 mean values are N, 122; W, 117; V, 131. The mean range in N for January, and the mean range in V for January and February are more than double the corresponding average values for 1915-1925.

The frequency distribution of absolute daily ranges recorded in 1926 is shown in Table V, which also contains the percentage distribution for the period 1915–1925.

TABLE VI.—PRINCIPAL MAGNETIC DISTURBANCES RECORDED AT ESKDALEMUIR, 1926.

Where the beginning of a disturbance has been marked by a "sudden commencement," the serial number is followed by an asterisk (*), and the time entered in the second column is that of the sudden commencement, estimated to the nearest minute. In other cases, the exact hour nearest the time at which disturbance may be regarded as having begun is entered in the second column. To the tabulated values of maximum and minimum the following have to be added :—N, 15000 γ; W, 4000 γ; V, 44000 γ.

† See monthly tables for further particulars of times of extreme values.

The intervals of maximum frequency are 70-79γ for N, 60-69γ for W, and 20-29γ for V. Thus, for W and V there is no change from 1925 in the interval of maximum frequency, but for N the interval is one higher than in the previous year.

There were 46 days, eight only of these being contributed by June, July, August, November and December, together, on which the daily range in either N or W was 160γ or more. The numbers of such days in the years 1915 to 1925 were 30, 47, 35, 56, 58, 36, 27, 32, 11, 10, 24. The numbers of days in 1926 on which the absolute daily range exceeded 199γ is outstanding ; for W and for V the number is not exceeded in any previous year, while for N the number is surpassed only by that for 1919. On 18 days in 1926 the range in each of the three components was 200γ or more.

Principal Magnetic Storms during 1926.—Particulars of the principal magnetic storms recorded during the year are given in Table VI. The magnetograms for the most highly disturbed days are not reproduced in this volume, but photographic copies may be obtained on application to the Director, Meteorological Office, Air Ministry, Kingsway, London, W.C. 2.

Remarks on Magnetic and Allied Phenomena, 1926.

January.—Conditions were distinctly more disturbed than during several preceding weeks. The 3rd, 5th, 21st, and 25th were the quietest days. The range in all three components, N, W, and V, exceeded 199γ on each of the days 22nd, 23rd, 26th, 27th. The storm of the 26th-27th was the largest since that of May 13-17, 1921. A notable feature of the month was the re-appearance on the sun's disc of two large spots which crossed the central meridian at 22·3d and 24·6d. The latter spot is stated[1] to have been one of the three largest observed in half a century.

A comparatively small " sudden commencement " (initial changes N, +18γ ; W, −2γ, +22γ ; V, −2γ) at 3d 22h 22m was followed by slight disturbance lasting for about 14 hours.

A somewhat prolonged spell of moderate disturbance began suddenly at 12d 22h 59m. The initial changes differed from those of the more common type of " sudden commencement " in that W decreased and remained below the undisturbed value for several hours. The disturbance, which was mainly of the undulatory type, continued until 16d 8h, the largest and most rapid changes occurring between 19h and 21h on the 13th and between 22h and 23h on the 15th.

The disturbance which began with a " sudden commencement " at 22d 15h 36m is noteworthy on account of the high absolute ranges in N and V, viz., 513γ and >388γ, respectively ; the range in W was 277γ. The most disturbed interval was from 22d 20h to 23d 2h, the minimum value in each component occurring shortly before 23d 1h.

No very prominent disturbance followed a small " sudden commencement " at 25d 17h 28m until the afternoon of the 26th, when one of the largest disturbances of the year developed. Moderate changes were in progress between 15h and 16h on the 26th, but the main part of the storm began, apparently, with rapid oscillatory movements at 16h 19m. Large and often extremely rapid changes occurred during the next twelve hours, and disturbance continued with diminishing intensity throughout the 27th and 28th. Maxima in all three components occurred near 19h and 21h on the 26th, while the minimum values were reached between 1h and 3h on the 27th. The largest and most rapid oscillatory changes occurred between 18h and 20h, 22h and 23h on the 26th, and between 0h and 3h on the 27th. A notable auroral display, with fine colour effects, was witnessed on January 26-27 in North America, Scandinavia, and Germany ; for details of aurora and of the magnetic records at other observatories, see *Nature*, Vol. CXVII, pp. 208, 234, 356, 366, 855, and *Met. Zs.*, Vol. XLIII, p. 356.

[1] *Nature*, Vol. CXVII, p. 171.

February.—Moderate disturbance occurred during the first five days and was followed by the quietest interval of the month, viz., 6th to 9th. The curves for the 7th and 8th are smoother than those for any day since December 26, 1925. A "sudden commencement" at 10d 5h 48 to 49m (initial changes N, +12γ; W, −8γ, +35γ; V, −2γ) was followed by somewhat slight disturbance on the 10th and in the early part of the 11th, but after 14h on the latter day the intensity of disturbance increased. Faint auroral streamers or rays were observed at Eskdalemuir near 21h on this day.

At 17d 22h 17 to 18m, in the course of disturbance which had been in progress since 15h on that day, there occurred what appears to be a "sudden commencement," the initial changes being N, −1γ, +47γ; W, +9γ; V, −6γ. Oscillatory changes of moderate magnitude occurred in N and W between 0h and 5h on the 18th. The changes in V were somewhat unusual; for the minimum, at 18d 0h 26m, was followed by a sharp rise of 86γ to the maximum at 18d 0h 46m. This maximum is only slightly in excess of that, at 17d 18h 27m, in the first part of the disturbance.

The second of the larger disturbances of the year began at about 23d 14h and continued until 25d 16h. It occurred, therefore, about 28 days after the large disturbance of January 26-27. There are points of similarity between the initial stages of these two disturbances; *e.g.*, in each case appreciable disturbance was in progress for an hour or two before a sharp oscillatory movement initiated large-scale irregularities. In the February disturbance the sharp oscillatory movement occurred at 23d 16h 27m, the magnitudes of the initial changes in the horizontal components being N, −45γ, +60γ; W, −33γ, +32γ. Although there was very considerable activity during the later hours of the 23rd and the early part of the 24th the main part of the disturbance occurred after noon on the 24th. The principal features of this storm are described in a letter to *Nature*, Vol. CXVII, p. 416, but, owing to the use of approximate scale values, the values of the ranges given in that account do not agree exactly with the values given elsewhere in this volume.

March.—The only day which approximated to a really quiet day was the 8th.

The first of the two more important disturbances of the month began, at 5d 10h 4m, with a "sudden commencement" of a sharply oscillatory nature. Greatest activity was confined to the interval 5d 15h to 23h, but disturbance did not cease until 7d 4h. A striking feature of the curves is the *massif* in N and in V (both components being considerably in excess of the undisturbed value) during the interval 15h 40m to 19h 50m on the 5th, the ascent to and descent from this elevated and highly oscillatory portion of the curves being abrupt. A corresponding feature does not occur in W, although sharp and large oscillations are shown during the interval mentioned. Further large oscillatory changes occurred in all components between 21h and 23h on the same day. Aurora was witnessed during the evening of the 5th at places in Scandinavia, France and Germany.[2]

The second of the larger disturbances of the month began between 10h and 11h on the 9th; it continued until about 13d 4h, greatest activity occurring between 9d 15h and 10d 8h. The most noticeable features are the rapid oscillatory movements between 9d 19h and 21h, and the very sharp minimum in V, associated with a marked depression in N, between 10d 1h and 2h. In the former interval the ranges were N, 537γ; W, 378γ; V, 252γ. The large oscillatory changes in this interval were associated with a bright aurora which was seen from Eskdalemuir and several other places in the British Isles, Scandinavia and France.[3]

A "sudden commencement" at 17d 21h 4m (initial changes :—N, −4γ, +34γ; W, +11γ; V, −2γ) marked the beginning of moderately large disturbance which, with some intermission between 19d 4h and 14h, continued until the 22nd.

Further moderately large disturbance occurred on 28th, 29th, and 30th.

April.—This, too, was a generally disturbed month, although there was only one outstanding disturbance. The quietest days were the 5th (until 22h) and the 29th.

The moderately large disturbance which developed shortly before midnight on the 5th and continued until the 10th is separated by an interval of about 27 days from the larger disturbance of March 9-13.

One of the larger storms of the year began with a large "sudden commencement" at 14d 14h 1 to 2m. The actual beginning of the "sudden commencement" occurred during a time-gap in the ordinary magnetograms, but the time of occurrence of the first impulse of the oscillatory movement on the record of dV/dt[4] is 14d 14h 1·6m. After the "sudden commencement" each component increased in value, although N and W made a temporary return towards the undisturbed value shortly after 15h. Each component attained the maximum value for the storm during sharp oscillations in the interval 16h 27m to 17h 7m. Further considerable activity occurred between 14d 22h and 15d 18h. W was in defect of the undisturbed value from 14d 20h to 15d 6h, V from 15d 0h to 15d 10h, and N mainly so from 15d 0h to 15d 12h. The minimum values of N and V occurred between 6h and 8h on the 15th, W attaining a secondary maximum in the same interval. After a comparatively quiet period extending from 15d 18h to 16d 3h there was a recrudescence of disturbance which continued throughout the night hours of the 16th-17th and then gradually subsided. This storm was, apparently, the fourth of a series in which successive members were separated by an interval approximating to the period of solar rotation. Aurora was observed at Cambridge and near Paris during the evening of the 14th[5].

Moderately large disturbance occurred throughout the intervals 21d 9h to 23d 18h, 24d 10h to 25d 18h, 26d 8h to 28d 2h. The disturbance of April 24-25 seems to be the last (recognisable) member of a series which occurred on the following dates:—1925, November 13-14, December 10; 1926, January 7, February 2-3, March 1-3, March 28-30.

May.—There were rather more and longer periods of fairly quiet conditions than in recent months. No noteworthy disturbance occurred after the 21st. The quietest days were the 1st, 2nd, 26th, 31st.

The first of the large disturbances of the month began with a prominent "sudden commencement" at 3d 21h 12m, the sudden initial changes being N, -3γ, $+63\gamma$; W, $+22\gamma$; V, -6γ. The disturbance reached its greatest intensity between 4d 16h and 5d 7h, but considerable activity continued until the 7th. All three components attained their maximum values between 17h and 18h on the 4th. The minima in N and in V occurred at 4d 22h 21 or 22m, while the minimum in W occurred, in the culmination of a prominent bay-shaped movement, at 4d 1h 29m. A prominent peak maximum in N was recorded between 16h and 17h, and between 19h and 20h, on the 6th.

Another rather large disturbance began about 9d 14h and continued until 14d 4h, 10d 2h to 10d 22h being the interval of greatest disturbance. Among the chief features of this disturbance are:—(*a*) a large wave movement in N between 10d 3h and 6h, the range between the maximum value at 3h 54m and the minimum at 5h 6m being 221γ, and (*b*) associated peak maxima in N and V between 15h and 16h and between 17h and 18h on the 10th.

There was almost continuous, moderate, disturbance from 19d 10h to 21d 24h.

---

[5] *Nature*, Vol. CXVII, pp. 601, 774.

June.—Although conditions were decidedly more quiet than in the first four months of the year there were few conspicuously quiet days. The smoothest curves are those for the 4th, 25th, and 27th.

The chief disturbance began with a " sudden commencement " at 1d 11h 9 to 10m, the magnitude of the sudden initial changes being N, +40γ (in at least two stages); W, −11γ, +26γ; V, −6γ. The maximum values of N and W occurred early in the disturbance, viz., between 14h 30m and 14h 50m on the 1st. The maximum in V near 1d 21h is not very prominent and is exceeded by the maximum at 2d 16h 59m. All three components were in defect of their undisturbed values during several hours after 1d 22h, the decrease in value of N and V shortly after the latter time being noticeably rapid. The minimum values in all three components occurred in the interval 2d 0h to 2d 3h. Near 2d 14h N rose rather rapidly from below to above the undisturbed value and reached a prominent maximum between 17h and 18h. After this, irregular disturbance subsided fairly quickly. This disturbance appears to be the last of a series which occurred at intervals approximating to 27 days; other members of the series are the disturbances of January 12-16, February 11-12, March 9-13, April 5-9, May 3-7.

Moderately large disturbance occurred throughout the interval 7d 11h to 11d 2h, but the intensity was less after 9d 8h.

A moderate disturbance of comparatively short duration was initiated at 23d 12h 57m by a " sudden commencement," the initial changes being N, −10γ, +32γ; W, −3γ, +13γ; V, −2γ.

July.—Except on the 5th, 7th, 8th, 27th, 28th and 31st only comparatively minor disturbance was recorded during this month. Minor disturbance was of very frequent occurrence, and on no day is there a complete absence of small irregularities. The interval from 20d to 23d, inclusive, was probably the quietest during the month.

The disturbances on the 5th, 7th, and 8th were of very moderate magnitude. That of the 5th may possibly be regarded as the sixth in a series of disturbances which occurred at intervals of about 27 days. The preceding members of this series occurred on January 22-23, February 17-18, March 17-19, April 14-15, May 9-14, June 7-11.

A larger disturbance occurred between 26d 23h and 28d 20h. Most activity is shown between 28d 2h and 6h, the interval in which V was considerably less than its undisturbed value. Aurora was observed between 5h 15m and 5h 40m, G.M.T., on the 28th, from ss. " Northwestern Miller " in (approximate) position 41°N, 69°W[6].

The last day was the most disturbed of the month. The disturbance, which began about noon on the 31st, continued until the early hours of August 2, although the principal phase may be regarded as terminating at August 1d 6h. Apart from fairly large wave movements in N and W between July 31d 22h and August 1d 1h, during which interval the principal minimum in V occurred, there were no particular noteworthy features. Attempts to find evidence of a connexion between the occurrence of individual magnetic disturbances and individual sunspots are often apparently disappointing, and may not be justifiable, but it may be noted that an important sunspot group, in a comparatively low latitude (11°S), crossed the sun's central meridian at July 30·0d[7]. On the other hand, the interval between the disturbances of July 5 and July 31-August 1 suggests that the latter may be a further member of the series beginning with the disturbance of January 22-23.

August.—This was a month of comparatively moderate magnetic activity. In addition to the rather large disturbance of the first day, moderate disturbance occurred on the days 9, 10, and 12 to 19 inclusive. The curves with least irregularities are those for the 8th and 23rd.

---

[6] *Marine Observer*, July, 1927.

[7] *Nature*, Vol. CXVIII, p. 205.

September.—Quiet conditions prevailed throughout the first five and last five days of this month. The curves for the 5th, 28th, 29th, and 30th are particularly free from irregularities.

Moderate disturbance between 6d 21h and 7d 1h was followed by a more considerable disturbance between 7d 20h and 11d 24h. The principal phase may be regarded as being confined to the interval 8d 10h to 9d 24h. The absolute range in V was 50 per cent. in excess of the range in either N or W. Prof. Störmer has published[8] details of a remarkable aurora curtain, of a violet-gray colour, observed and photographed between 21h and 22h on September 8. According to Prof. Störmer's determinations this curtain, at 8d 21h 37m, extended about 200 km. upwards from the lower border at the unusual altitude of 30 km., and was situated slightly north to north-west of Lerwick. The beginning of a fairly large wave movement is seen on the Eskdalemuir magnetograms between 21h 30m and 22h, the value of each component decreasing in that interval, but there is no unusual activity.

A "sudden commencement" at 14d 8h 44m initiated prominent disturbance which continued until 17d 9h, although irregular changes were unimportant between 15d 5h and 12h. The largest changes occurred between 18h and 24h on the 14th (ranges: N, 240γ; W, 192γ; V, 178γ), between 14h and 24h on the 15th (ranges: N, 305γ; W, 277γ; V, >340γ), and between 16d 20h and 17d 2h (ranges: N, 194γ; W, 98γ; V, 92γ). In the second, and most disturbed, of these intervals the maximum in V is very much more conspicuous than the minimum. Aurora is reported to have been seen during the evening of the 15th from Oban, from the Isle of Man, and from near London. At Eskdalemuir, a broad band of diffuse light, extending from north-east to west-by-north, was first observed at 20h 20m. The altitude of the upper part of the band was about 40°. Streamers or rays, and drapery effects, were seen shortly after 20h 30m. A well-marked fold or curtain formation towards north-east persisted for some minutes, stars being visible below. Towards west the main feature was a glow. At 21h 5m the display seemed to be fading. Between 22h 25m and 23h, although there was no general illumination due to moonlight, the aurora was less distinct than in the earlier stages; but this phase was notable for extremely rapid flickerings and pulsatory effects which *appeared* to progress upwards. The extreme elevation of any part of the aurora was estimated to be about 45°. The magnetic changes in the interval during which aurora was observed were rather less active than in the immediately preceding hours. N and W were mainly below the undisturbed value. Between 15d 22h and 23h there was a rather large depression in N—this component reaching the lowest value for the storm in this interval—and a less prominent depression in V. The record of the rate of change of vertical force shows intense short-period pulsatory movement between 22h 16m and 23h 5m, *i.e.*, throughout the interval when pulsatory auroral effects were noticed.

On the 17th, after a few hours of quiet conditions, a "sudden commencement" of moderate magnitude occurred at 22h 7m. The disturbance thus initiated became prominent after 18d 12h, and may be regarded as continuing throughout the 19th and culminating in the storm of the 20th and 21st. In this storm, which was more severe in every respect than the disturbance on the 14th-16th, the most highly disturbed interval was from 21d 4h to 22h. A noteworthy feature is a large depression in the value of N and of V, associated with an enhanced value of W, between 5h and 9h on the 21st. The minimum values of N and V, and the maximum value of W, were reached during this interval. The maximum values of N and V were attained in the course of a very prominent sharp oscillation between 15h 30m and 16h on the 21st. Reference may be made to remarks in *Nature*, Vol. CXVIII, p. 495, as to a possible connexion between this storm and causes associated with the appearance of an important sun-spot group.

---

[8] *Beitr. z. Geophysik*, Vol. XVII, 2, p. 254.

October.—There were no outstanding features in the periods of moderate disturbance which occurred during the early days of the month. Conditions were quiet on the 10th, and during several hours of the 1st, 2nd, 4th, 5th, and 9th. A slight disturbance began at 11d 4h 49m with a small "sudden commencement."

A large storm, one of the most noteworthy storms of the present solar cycle, began with a prominent "sudden commencement" at 13d 19h 23m, the magnitudes of the initial sudden changes (from 19h 23m to 19h 29m) being N, $+39\gamma$; W, $+19\gamma$; V, -5γ. The magnetograms show movements of fairly considerable size during the six or seven hours following the "sudden commencement,' especially between 0h and 2h on the 14th ; but the greatest development of the storm occurred after 14d 20h. The latter time marks the beginning of an interval of several hours duration in which N, W, and V were considerably below the undisturbed values. The depression in V was particularly large from 14d 23h to 15d 4h. For nine or ten hours after the occurrence of a rapid oscillatory movement at 15d 7h 37m the curves show intense short-period pulsatory movement, sometimes of considerable amplitude in N and W. The absolute maximum value, for the storm, in each component occurred near 18h or 19h on the 15th. Between 15d 19h and 20h there were three or four very large and rapid oscillations, accompanied by a most pronounced decrease in the value of each component. The ranges recorded during this interval were : N, $>719\gamma$; W, $>957\gamma$; V, 570γ ; but as the N and W traces left the paper at both the upper and lower limits the recorded ranges in these components are probably considerably less than the true values. From 20h to 22h the changes were, comparatively speaking, less violent ; N and W remained much below the undisturbed value, while V made an irregular recovery. Further large and rapid changes took place between 15d 22h and 16d 3h, and throughout this interval the value of each component was considerably less than the undisturbed value, apart from a few brief excursions in N and W. Prominent sharp maximum turning points in N occurred at 22h 13m, 23h 0m, 23h 46m, on the 15th and at 0h 29m on the 16th, the intervals between successive maxima thus being 47, 46, 43 minutes. The period of recovery was marked in its earlier stages by almost continuous, comparatively small, oscillations which continued until 16d 17h.

Aurora was observed at Eskdalemuir during both nights of the maximum phase of the storm of October 13-16. The sky was rather cloudy during the early part of the evening of October 14, but a glow was seen low down in the north at 19h and again at 20h 30m. No further look-out was kept until 23h 20m when a good auroral display was seen to be in progress. There were then an arch, perhaps 5° above the horizon, to north, and numerous streamers, the tops of which reached an elevation of 55° or rather more. Flickerings, or transient patches of luminosity were noticed at an elevation of 60° to 70°. The interval of greatest brightness and activity was from 23h 27m to 23h 38m, the concentration being mainly between north and north-east. At about 23h 30m red coloration was noticed above a thin cloud layer to north-north-east. What appeared to be a sheaf of streamers reaching an elevation of about 50° developed near this azimuth. The upper half of the sheaf was of a distinctly red colour which persisted until 23h 38m to 40m. By 23h 45m, the brightest part of the display was located towards north-north-west, but the activity was apparently less than that observed earlier to north-north-east. At midnight and shortly after, less detail was visible. The magnetic changes between 23h and 24h consisted of oscillations of considerable magnitude in N and W ; in V, a general decrease, which had been in progress since 20h, was accelerated shortly before 23h and within a few minutes the recording spot of light passed off the paper. From then until 3h 30m on the 15th, excluding three brief intervals of a few minutes each, V was at least 270γ below the quiet-day value. At about 4h 30m on the 15th a glow, partly obscured by streaks of cloud, was seen to north.

Aurora equalling in grandeur that of the night of October 15-16 is probably rarely seen from this locality. The phenomenon was noticed first at 19h ; it was still in progress at 0h 30m on October 16, and was observed at Edinburgh between

2h and 3h. Among the chief features noted at Eskdalemuir were the repeated occurrence of a great arch extending from north-north-east to west-by-south horizon through zenith, and of approximately east-west intermittent bands or streaks well to the south. These bands were occasionally very bright and at times their estimated elevation from south was only about 40°. Numerous streamers and a general arched glow near the horizon from north-east to north-west, were observed at 19h. The upper limit of the streamers rapidly increased and ultimately reached to the zenith. In the early stages there were curtain effects at a low elevation to north, one of the most prominent occurring at 19h 10m. Somewhat later the activity in the extreme north seemed to diminish. There were, however, prominent developments and flickerings from east and west up to a corona formation near the zenith. Red coloration was seen towards west at 19h 30m, and at about this time considerable activity was noticed to south. At 20h there was less detail but the whole northern sky appeared to be filled with thin auroral luminosity, through which stars were visible. It was during this first phase of the aurora, 19h to 20h, that a large decrease, accompanied by large and rapid oscillations, occurred in all three components of the earth's magnetic field at Eskdalemuir. For nearly an hour after 20h there was apparently little activity in the extreme north, but there were intermittent streaks and bands passing from east-by-north to west-by-south through zenith and extending towards south. The bands were most distinct at 20h 21m. Shortly before 21h the approximately east-west overhead arch became more prominent and wider, the development from the east horizon being very noticeable. This arch effect, although varying somewhat in character, remained the dominating feature of the display. At 21h 45m, the elevation of the northern edge of the arch was about 52° (from north). There were east-west flashes and streaks well to the south, but very little display was visible to the north below the arch. As remarked above, the magnetic changes between 20h and 22h were less violent than those recorded immediately before and after this interval. At 22h 10m the display was mainly from the zenith towards north; its appearance suggested a cascade, directed northwards, from a corona located slightly to the south and east of zenith. Red coloration was noticed in the upper parts of the display towards east and west at 22h 14-15m, and at 22h 19-20m there was a curtain low down to north-north-east spreading westwards. The corona formation near the zenith continued prominent. Flickerings and stabbings from east and west seemed to reach up to the corona. Shortly after 23h there was further activity far to the north. From 23h 30m to 43m the sequence of changes bore a general resemblance to that from 22h 10m to 15m. A general arch effect developed, apparently growing from near zenith towards north and reaching down to an elevation of about 55° at first, and then becoming lower and more diffuse. There was also southward extension of the arch, with flickering on the southern extremity. Red colour was seen to east-north-east and to west at 23h 43-45m.

Reference may be made to published reports of solar activity observed on October 13[9] and to accounts of aurora witnessed elsewhere on October 14-16[10]. Interruption of the radio-transmission (beam signals) service with Canada occurred during the storm of October 13-16[11].

Rather prominent disturbance occurred between 12h and 22h on the 19th. A larger disturbance occurred between 25d 2h and 20h; it began with a small "sudden commencement" at 24d 6h 23m.

November.—Moderate disturbance occurred during the first three days of the month. From the 7th to the 20th conditions were mainly quiet, apart from a very slight disturbance initiated by a "sudden commencement" at 11d 17h 48m.

---

[10] *Nature*, Vol. CXVIII, p. 679; *Meteor. Mag.*, Vol. 61, p. 243.; *Met. Zs.*, Vol. XLIII, p. 502; *Marine Observer*, October, 1927.
[11] *Nature*, Vol. CXVIII, pp. 662, 803.

In the course of otherwise very moderate disturbance on the 21st (*i.e.*, about 26 days after the disturbance of October 25) rather prominent changes occurred in N and W between 21h and 22h; at the culmination of these changes N was approximately 100γ above and W 105γ below the undisturbed value.

The largest disturbance of the month occurred about 27 days after the smaller disturbance of the 1st-3rd. Disturbance was greatest between 28d 16h and 29d 18h. The maximum in V on the second day (also the maximum value for the disturbance) is sharp and the time of occurrence, 13h 30m, is rather early. It is associated with rather sharp oscillatory changes in N and W.

December.—Only slight or very moderate disturbance occurred during the first fourteen days. The 8th and 9th were the quietest days of the month.

Comparatively slight disturbance followed a "sudden commencement" at 3d 22h 2m. A somewhat similar, but smaller and slower, movement occurred at 3d 19h 46m.

Larger disturbance occurred between 15d 14h and 17d 4h, between 20d 17h and 21d 5h, and between 21d 15h and 21d 23h.

A "sudden commencement" at 23d 8h 35m marked the beginning of a comparatively moderate disturbance which is, however, the largest recorded in this month. The maximum phase occurred between 23d 12h and 22h, but smaller disturbance continued throughout the following day. The maximum value of N and the minimum value of V, for the disturbance, occurred shortly after the "sudden commencement." The sharp principal maximum in V at 23d 16h 38m is followed by a sharp secondary maximum at 23d 18h 46m.

Further fairly large disturbance occurred between 27d 13h and 28d 2h, and between 28d 16h and 30d 2h.

Readings in millibars at exact hours, Greenwich Mean Time.

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 mb. is written 005·6. This rule does not, however, apply to monthly means.

Readings in degrees absolute at exact hours, Greenwich Mean Time.

178. Eskdalemuir : Louvred Hut : h_t (height of thermometer bulb above ground) = 0·9 metres. **January, 1926.**

* Computed from the mean temperatures and the mean relative humidities. † Mean of the column. ‡ Mean of the row.

Percentages at exact hours, Greenwich Mean Time. Determined as explained on page 14.

199. Eskdalemuir : Louvred Hut : h_t (height of thermometer bulbs above ground) = 0·9 metres. **July, 1926.**

* Computed from the mean temperatures and the mean relative humidities. † Mean of the column. ‡ Mean of the row.

Percentages at exact hours, Greenwich Mean Time. Determined as explained on page 14.

201. Eskdalemuir : Louvred Hut : h_t (height of thermometer bulbs above ground) = 0·9 metres. **September, 1926.**

† The totals and durations for individual months are printed in the tables on the following pages.

NOTES ON RAINFALL.

208. Eskdalemuir. **1926.**

Notable Falls of the Year.

(*a*) A fall worthy of notice occurred on August 10th, when 5 mm. fell in 8 minutes. On August 20th a fall of 5 mm. in 10 minutes took place.

(*b*) Details of the greatest continuous falls are as follows :—

Date.	Amount. mm.	Duration. hrs.
January 23rd	32	9·2
February 14th—15th	31	17·0
April 14th—15th	35	16·7
July 21st	26	7·0
August 20th	32	7·5
September 14th—15th	32	7·6
September 20th	36	9·3
October 8th—9th	29	6·2
November 4th—5th	73	21·5
November 18th—19th	27	13·5

Wet Periods.

(*a*) There was one "rain spell" (*i.e.*, a period of fifteen or more consecutive days on each of which 0·2 mm. or more of rain fell), viz., August 9th to August 24th.

(*b*) There was one "wet spell" (*i.e.*, a period of fifteen or more consecutive days on each of which 1·0 mm. or more of rain fell), viz., August 9th to August 23rd. The period February 14th to February 28th failed to classify as a "wet spell" in having no rain on the 28th.

Dry Periods.

(*a*) There were no periods of "absolute drought" (*i.e.*, fifteen or more consecutive days on each of which less than 0·2 mm. of rain fell), or of "partial drought" (*i.e.*, twenty-nine or more consecutive days, the mean rainfall of which did not exceed 0·2 mm. per day).

(*b*) A relatively dry period was March 12th to March 28th, during which only 3·3 mm. of rain fell.

Amounts in millimetres, for periods of sixty minutes, between the exact hours, Greenwich Mean Time.

209. Eskdalemuir : H_r (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + h_r (height of receiving surface above ground) = 242·0 metres + 0·4 metres. **January, 1926.**

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 235 metres + 15 metres.

March, 1926.

Direction expressed in degrees from North ($E = 90°$, $S = 180°$, $W = 270°$, $N = 360°$). Speed in metres per second.

237. Eskdalemuir : H_a (height of anemograph above M.S.L.) = Height of ground above

* Anemometer under adjustment. † Mean for 27 days only.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 235 metres + 15 metres.

May, 1926.

† Instrument under adjustment. ‡ Mean for 30 days only.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 235 metres + 15 metres.

July, 1926.

† Instrument under adjustment. ‡ Mean for 29 days only.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 235 metres + 15 metres.

September, 1926.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 235 metres + 15 metres.

November, 1926.

NOTES.—(1) The initial 2 or 3 of the readings is omitted, *i.e.*, 275·0 is written 75·0.
(2) The minimum refers to the interval from 18h. the previous day to 7h. on the day to which it is entered. Mean for July is for 30 days only.
(3) Annual Mean 275·3.

248. Eskdalemuir. **January, 1926.**

NOTE.—The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used : z +, Indeterminate, positive value ; z—, Indeterminate, negative value ; z ±, Indeterminate in magnitude and sign.

(*a*) Mean of all positive readings. (*b*) Mean from all complete days using both positive and negative readings.

Mean Values for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used: z + Indeterminate, positive value ; z — Indeterminate, negative value ; z ± Indeterminate in magnitude and sign.

(a) Mean from all positive readings. (b) Mean of all complete days using both positive and negative readings.

POTENTIAL GRADIENT (reduced to level surface): DIURNAL INEQUALITIES (in volts per metre).

The departures from the mean of the day are adjusted for non-cyclic change.

Annual Mean Character Figure 0.98.

Explanatory Note.—The electric character of the day is indicated by the figures 0, 1, or 2, according to the character of the trace of the electrograph as regards negative potential gradient. The explanation of these symbols is as follows :—

0, denotes a day during which from midnight to midnight no negative potential was recorded.

1, denotes one or more excursions of limited duration to the negative side of the scale.

2, denotes negative potential extending in the aggregate over 3 hours or more.

" *a*," denotes that within the 25 periods of 60 minutes for which an estimate of the mean potential gradient has to be made in the process of tabulation there was in no case a range of potential gradient in the open exceeding 1000 volts.

" *b*," denotes that a range of potential gradient in the open exceeding 1000 volts was reached in at least one but in fewer than six of the 25 hourly periods referred to above.

" *c*," denotes that a range of 1000 volts or more occurred in at least six of the 25 hourly periods.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

264. Eskdalemuir. (X.) 15,000 γ (·15 C.G.S. unit) + **January, 1926.**

§ For explanation *see* page 145. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

§ For explanation *see* page 145. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

† Mean of 29 days; 17th and 19th omitted. * No record.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

276. Eskdalemuir. (X.) 15,000 γ (·15 C.G.S. unit) + **April, 1926.**

§ For explanation *see* page 145. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

290. Eskdalemuir. (Z.) 44,000 γ (·44 C.G.S. unit) + **July, 1926.**

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

TERRESTRIAL MAGNETIC FORCE : VERTICAL COMPONENT.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

294. Eskdalemuir. (Z.) 44,000 γ (·44 C.G.S. unit) + **August, 1926.**

Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

§ For explanation *see* page 145. Q denotes an " International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

Mean values for periods of sixty minutes centred at the Hours of Greenwich Mean Time.

§ For explanation *see* page 145. Q denotes an "International Quiet Day," while D denotes a disturbed day used for the computation of Tables 318–329.

DIURNAL INEQUALITIES OF THE GEOGRAPHICAL COMPONENTS OF MAGNETIC FORCE.—"ALL" DAYS.

(Not corrected for the effect of the North Force on the West Magnetograph, or *vice versa*, or for the effect of the Horizontal Force on the V.F. Balance.)

Departures from mean of the day adjusted for non-cyclic change.

NORTH COMPONENT (*all days except March* 17, 19).

DIURNAL INEQUALITIES OF THE MAGNETIC COMPONENTS, DECLINATION, INCLINATION, AND HORIZONTAL FORCE.

"ALL" DAYS.

Departures from mean of the day adjusted for non-cyclic change.

DECLINATION (measured positive towards the West) (*all days except March* 17, 19).

DIURNAL INEQUALITIES OF THE MAGNETIC COMPONENTS, DECLINATION, INCLINATION AND HORIZONTAL FORCE.—INTERNATIONAL QUIET DAYS.

Departures from mean of the day adjusted for non-cyclic change.

DECLINATION (measured positive towards the West) (*Quiet Days*).

INTRODUCTION.

SITE.

Valentia Observatory derives its name from the fact that it was originally established on Valentia Island in 1867. It was removed to the mainland in March, 1892, and now lies in a direct line between the old site on Valentia Island and the town of Cahirciveen, about 2½ miles (4 km.) north-east from the former, and three-quarters of a mile (1 km.) south-west of the latter. It is quite remote from any other buildings. The general character of the country surrounding the Observatory is hilly. The eastern bank of the Cahir river is about 150 metres to the westward, and in that direction there is no very high ground between the Observatory and the open sea, some 3½ miles (6 km.) away. To the north-west, however, are hills varying in height from 400 (120 m.) to 900 feet (275 m.), the highest being less than 3 miles (5 km.) distant. These are only separated by a narrow gully running in a N N W direction from other hills equally high, which stretch away to the northward: the nearest of these is but little more than a mile (1½ km.) from the Observatory. Beyond the town of Cahirciveen to the north-east the river opens out considerably, and the country in this direction becomes an open boggy basin, rising by only a gentle gradient. Southward of this, however, it soon rises again, and at about a mile south-east of the Observatory it culminates in a hill upwards of 1,245 feet (380 m.) in height. Still further south it opens out once more to a distance of nearly 5 miles (8 km.) from the Observatory, where there is a range of hills running east and west, and varying in height from 400 (120 m.) to 1,300 feet (400 m.). To the south-west there is an opening to the sea, between Valentia Island and the mainland; and the circle of hills is completed by those on the island itself, the highest of which is about 800 feet (240 m.) high, and bears about west-south-west from the Observatory. Photographs of the Observatory building, together with a site plan, showing the disposition of the various instruments were reproduced in the Introduction to the 1923 volume.

METEOROLOGY.

The elements dealt with in the following tables are : atmospheric pressure, air temperature, humidity, rainfall, sunshine, wind speed and direction, minimum temperature on the grass, together with a diary of cloud and weather.

Pressure and Temperature.—The photographic barograph and thermograph are installed in a room on the ground floor of the Observatory tower. The standard Fortin barometer, from which the control readings at 9h, 15h and 21h are taken, is mounted in the same room beside a window which faces the north-east. The stems of the dry and wet bulb thermometers pass out into the screen placed against the north wall of the tower. Close to the bulbs of these thermometers are the bulbs of the standard thermometers from which the control readings at 9h, 15h and 21h are taken.

Rainfall.—The Beckley raingauge and the 8-inch (20·3 cm.) check gauge are placed in a railed-off enclosure about 40 metres to the north of the tower.

Sunshine.—The recorder is cemented to a wooden rail on the roof of the tower. The exposure is satisfactory.

Wind, Speed and Direction.—The measurements of Wind Speed and Direction, as given in Tables 408-419, were formerly obtained from the Robinson Cup Anemograph on the roof of the Observatory tower. Commencing with the 1926 values, given in the present volume, all measurements of Wind Speed and Direction are taken from the records of the Dines Tube Anemograph. This instrument stands in an open field, about 250 metres S E by E of the Observatory tower. The field slopes northwards to the river Cahir. About 1 mile ($1\frac{1}{2}$ km.) to the south-east and in an approximately direct line with the highest point (1,245 feet) is the hill Bentee which extends for some little distance in a northerly and south-westerly direction. A description of the surrounding country has already been given.

Minimum Temperature on the Grass.—The grass minimum thermometer is of the type described on p. 12. It is exposed over short grass in the field enclosure It is set at 18h and read at 7h on the succeeding day, the observation being entered to the day of reading.

Visibility.—A list of the objects used for visibility observations and their distances and bearings from the point of observation is given on p. 259.

Notes on the Meteorological Summaries.

Pressure.—The mean pressure for the year was 0·3 millibar below normal. Of the monthly mean pressures five were higher and seven were lower than normal. The departures were in some cases considerable ; December, for example, having an excess of about 19 millibars and March about 5 millibars, while November showed a deficiency of about 13 millibars.

The highest pressure of the year, 1,045·2 millibars, was recorded on the 24th December and the lowest 964·6 millibars, on the 20th November, giving a total range for the year of 91 millibars. February and November had ranges of more than 50 millibars. The smallest range for any month was 25·5 millibars recorded in September.

The diurnal inequality of pressure for the year as a whole shows the usual well marked double oscillation with maxima at 11h and 21h of which the second is the principal one ; and minima at 5h and 16h, the principal of these two being the morning one. In the inequalities for the individual months it is found that the double oscillation is much more prominent in some months than in others. The greatest constancy is seen in the morning minimum which is the principal one for nine months of the twelve and occurs always at 4h. 5h or 6h. The afternoon minima in the winter and equinoctial months occur usually at 15h, 16h or 17h ; in the summer months the time is 17h or 18h. For eight months the morning maximum appears either at 11h or 12h, and in two of the summer months it occurs at 9h ; while in August it is as late as 13h. The night maximum in nine months out of the twelve occurs at 21h or 22h ; in January it appears at 20h, in November at 19h, and in December at midnight.

The range of the mean inequality for the year is ·95 mb. while for the months considered individually it varies from ·85 mb. for October to 1·49 mb. for January. These ranges represent only the regular periodic changes in pressure and are small compared with the ranges obtained from the mean values of the daily maximum and minimum pressures found in Table 352, which vary from 4·59 mb. for July to 13·60 mb. for January.

Comparison of diurnal inequalities may be made by means of analysis into harmonic components. The details of the Fourier analysis of the diurnal inequalities for the year 1926 are given in Table A. The figures in the line immediately following the monthly values are the arithmetic means for the year of the monthly amplitudes. On account of the very large changes in phase throughout the year in some of the terms the amplitudes obtained from the annual inequality are not adequate as measures of the effectiveness of such terms relative to others whose phase angles show less variation from month to month. In these cases comparison of the arithmetic means of the monthly amplitudes is more satisfactory.

The most important terms are the 24-hour and 12-hour terms. For the year considered as a whole the amplitude of the 24-hour term is considerably higher than for the period 1871-1882 whereas the arithmetic mean for the twelve months is about the same as for the period, which points apparently to a smaller variation than usual in the 24-hour term phase angles throughout the year. The seasonal amplitudes show a considerable variation, the winter one being the highest and that for the equinoxes the lowest. The 24 hour term always shows wide and somewhat irregular variations from month to month both in phase and amplitude.

The 12-hour term is more nearly constant during the year, both in amplitude and phase. For 1926 the amplitudes are higher than average. The highest phase angle appears in winter and the lowest in summer. The high winter phase angle appears to be the normal state of affairs at Valentia which differs in this respect from most British stations.

In the mean inequality for the year the 8-hour term appears almost negligible when its amplitude is compared with those of the two terms already considered, but that this is due mainly to the very wide variations in phase of this term during the year is seen quite clearly by reference to the individual months. For all the winter months the 8-hour term amplitude is of the same order of magnitude as the 24-hour term amplitude. At other seasons it is relatively unimportant. The phase of this term has a fairly regular seasonal variation, changing somewhat rapidly at the equinoxes by approximately two right angles. The effect of the phase variation at this season is seen in the very small amplitude which appears for the equinoctial mean. In the 6-hour term amplitudes are small throughout and for this reason not very much weight can be attached to the individual phase angles. Nevertheless it is possible to detect an annual variation in the latter in which the movement is generally in the opposite sense to that of the 8-hour term.

Temperature.—The mean temperature for the year 1926 was 0·46a (0·83° F.) above normal. The highest temperature of the year, 298·3a (77·5° F.), was registered on the 13th July. Very low temperatures were not common, the freezing point being passed only on nine days. The lowest temperature 270·1a (26·8° F.), was registered on the 27th December. The full range of temperature for the year was thus 28·2a (50·8° F.). For the individual months mean temperatures did not differ greatly from normal. February, with an excess of 2·05a (3·69° F.) showed the greatest departure. The monthly ranges of temperature varied from 9·2a (16·6° F.) in February to 21·4a (38·5° F.) in October.

The mean diurnal inequality for the year shows a single oscillation in the 24 hours with its maximum at 14h and its minimum at 5h and with a range of 2·78a (5·00° F.). Each of the monthly inequalities has a well marked single oscillation with its maximum at 13h, 14h or 15h, except that for June which has its maximum at 16h. The time of minimum does not show the same constancy. In January it is 3h and in other months we find it varying from 4h in November to 8h in February. In the summer months it occurs at 5h, and in April and September at 6h.

The harmonic analysis of the monthly and seasonal diurnal inequalities of temperature is given in Table B. The 24-hour term is in all cases predominant. Neither in the 24 hour term nor in the 12-hour term is there any very large variation in phase angle throughout the year, the effect of this being seen in each case in the slight differences between the mean amplitude for the year and the amplitude computed directly from the annual inequality. The highest of the seasonal amplitudes for the 24-hour term is found in summer, as is usual, but this amplitude is itself below normal, the amplitudes at equinox and summer being higher than usual. The phase angle is least in winter and greatest in summer whereas winter should normally have a slightly larger phase angle than equinox and summer should have the least. In the present case the winter phase angle is rather below normal while summer and equinox have each approximately the phase angle which is normal for the other. For the 12-hour term the seasonal values follow the normal sequence in amplitude ; but here again the summer and winter values are low. Phase angles both for equinox and summer, normally about the same, are high, the summer one in particular having a value nearly twice the normal.

The 8-hour term amplitude for the year is so small as to be negligible compared with the other terms but this is due in large measure to the variations of phase angle in this term from month to month. There is approximate opposition of phase as between winter and summer while for the equinoctial months a rapid change takes place from winter to summer values. The equinoctial amplitude thus appears much smaller than those for the individual months which make up this season. The winter and summer amplitudes are comparable in magnitude with those of the corresponding 12-hour terms, the summer 8-hour term amplitude being, in fact, greater than the 12-hour term amplitude. The seasonal changes in the 8-hour term accord fairly well with those found in a normal year.

The 6-hour term amplitude is greatest at the equinoctial seasons and smallest in summer but variable phase angle has much to do with the small winter and summer amplitudes.

Relative Humidity.—The highest mean daily value of the relative humidity was 97·4 per cent., recorded for the 16th September. The lowest value was 55·7 per cent. for the 12th January. The highest mean daily vapour pressure was 20·0 millibars for the 15th July and the lowest was 4·4 millibars for the 15th December. The mean relative humidity for the year was 2·3 per cent. below normal and the mean hourly values for the year show a range of 8·7 per cent. a difference from the normal range of only 0·1 per cent. Of the separate months, only July, August and September had mean relative humidities higher than normal. The deficiency for October was as much as 6·4 per cent. and for March 6·2 per cent. The greatest excess, on the other hand, was 2·8 per cent. for September. The diurnal inequality for the year shows a maximum in the early morning and a minimum in the afternoon ; neither of these is very sharply defined as to time of occurrence. There is only one well marked oscillation in the 24 hours. The individual months show, on the whole, similar features but there is a slight indication in some cases of a secondary maximum.

Rainfall.—The total rainfall for the year was 9 per cent. lower than normal, the actual deficiency being 138 millimetres. The month with the highest rainfall was January, with 266 millimetres, or 79 per cent. more than normal. November had 53 per cent. more than normal. The lowest monthly total was that for December, the 36 millimetres which fell during that month being only 22 per cent. of the normal amount. The rainfall for March was also very low being 39 per cent. of normal. The greatest hour's rainfall was 11·3 millimetres which fell between 3h and 4h on the 30th August.

Bright Sunshine.—The total amount of bright sunshine for the year 1926 was about 11 per cent. less than the normal. Only four months had more than average sunshine, the greatest excess being about 18 per cent. for January and April. The most notable deficiency was for February, the total sunshine for this month being less than one-half the average amount. The greatest recorded sunshine for any one day was 14·5 hours, on the 15th July. The day with the greatest proportion of the total possible sunshine was the 24th April with 94 per cent., the actual sunshine recorded on this day being 13·5 hours.

Wind Speed.—The mean monthly wind speeds were higher than average, except those for July and December, which had wind speeds below normal. Gales were experienced on three days in February, and one day in December.

The highest hourly wind speed recorded was 21 metres per second (41 miles per hour) on the 5th February, on which day occurred also the highest gust of the year 33 metres per second (70 miles per hour).

Grass Minimum Temperature.—The mean of the monthly means given in Table 422 is 278·9a (42·6° F.). For no single month is the mean grass minimum temperature lower than the freezing point of water. The lowest value recorded in seven months out of the twelve is below the freezing point.

Cloud and Weather.—The mean amount of cloud at all observation hours was 7·6. The most cloudy month was February, with a mean cloud amount of 8·7. The month with least cloud was March with a mean of 6·6. The mean values at the individual observation hours for the whole year show a steady fall in cloud amount from 7h to 21h. The number of occasions of cloudless sky during 1925 was only 31 in more than 2,000 observations ; on no day in the whole year was the sky without cloud at all observation hours.

Visibility.—The objects used, together with their actual distances and bearings from the point of observation, the observatory tower, are given in the table below.

The observations of visibility in tables 423–434 refer to visibility in a landwards direction. Entries of " l " and " m " are made :—

(*a*) When Croaghmarhin Mountain (an object seen across Dingle Bay at a distance of 25,500 metres, bearing 325°, used for determining visibility in a seawards direction) is clearly visible and there is reason to believe that the range of visibility in a landwards direction is as good as, or nearly as good as, visibility seawards.

(*b*) When Croaghmarhin Mountain is invisible but there is reason to believe from the appearance of Drung Hill (see table below) that the range of visibility landwards is greater than the range seawards and is sufficiently good to justify the entry made.

There is a complete absence of industrial activity within a radius of about a hundred miles from the Observatory; the observations are therefore not affected by smoke pollution of the atmosphere.

When the mountains used as objects at 3,500 metres and beyond are cloud capped the appropriate entries for the range of visibility are determined by the clearness or otherwise with which the lower parts of the mountains can be seen.

TERRESTRIAL MAGNETISM.

Notes on the Magnetic Observations for the Year 1926.

Absolute observations of declination, horizontal force and inclination were made weekly at the Valentia Observatory during the year 1926. The instruments in use were the same as in previous years, namely, the Dover unifilar, No. 139, with collimator magnet 139A and mirror magnet 139C, and the Dover dip circle, No. 118. The mean times of observation were 10·22 for the declination, 11·41 for the horizontal force and 14·30 for the inclination, all according to Greenwich Mean Time. In the individual observations the greatest departure from the mean time in any element was 5 minutes. The deflection of the mirror magnet was measured for two distances of the collimator magnet, namely, 30cm. and 40cm. The complete deflection observation consisted of eight readings of the mirror magnet. The distribution constant, P, used for 1926 was computed from the mean deflections for 30cm. and 40cm. for the seven years 1919–1925 inclusive. The mean P so obtained was 7·41. The moment of the collimator magnet has decreased at the rate of about 1·5 unit per annum.

The values of the declination, horizontal force and inclination obtained in the absolute observations are given in detail in Table C. All the observations made are included in this table, but in Table D the mean monthly values are computed from only such of the absolute observations as were taken at times subsequently found, by reference to the quarterly list of daily "magnetic characters" published by authority of the International Meteorological Committee, to be free from serious disturbance. Observations in Table C taken at disturbed times, and not, therefore, utilised for the mean values in Table D, are marked with an asterisk. The north, west and vertical components and the total force for each month and the year are computed from the corresponding mean values of the observed elements.

Westerly declination has diminished by 1′·6 as compared with 1925. From 1924 to 1925 the decrease was 12′·5 and in the previous 12 months 11′·6. The average annual decrease for the five years 1915–1920 was 9′·2, and for the five years 1910–1915 it was 8′·2. During the five years ending in 1926 the average annual decrement is 11′·1 so that the rate of the eastward movement of the magnetic needle appears to be increasing slowly.

Northerly inclination increased by 0′·1 from 1925 to 1926. The corresponding change for the preceding year was −0′·6, and for the year previous to that −0′·9. From 1910 to 1915 the average yearly decrease was 1′·0 and from 1915 to 1920 0′·5. For the five years 1921–1926 the average change per year is −0′·7. Inclination, therefore, continues to diminish at a slow rate.

It was remarked in these notes for the year 1922, that since the year 1920 the horizontal force had appeared to be increasing slowly whereas previously it had shown a steady decline from year to year. For the five-year period 1910–1915 the average annual decrease was about 5γ and for the period 1915–1920 about 6γ, while from 1920 to 1921 an increase of 8γ appeared, followed the next year by a further increase, but only of 1γ. The mean for 1924 showed a further increase of 2γ over that for 1923, but the mean value of H for 1925 was lower by 5γ than that for 1924, so that the slow rise in the horizontal force observed for the previous four years had apparently been checked.

The mean horizontal force for 1926 is again lower than that for 1925 by 14γ.

Reference to the last column of Table D shows that the reversal of the annual change in the horizontal force from 1920 onwards was not accompanied by any such reversal in the total force. From 1910 to 1915 the average yearly change in the total force was -49γ, and from 1915 to 1920 it was -33γ. From 1920 to 1925 the mean annual change is again -32γ, so that the total force has continued to decrease at a fairly uniform rate. The individual changes from year to year as shown in the table are somewhat irregular, but this may be due in considerable measure to instrumental uncertainties. The total force is computed from the horizontal force and the inclination, using the formula $T = H \sec I$, so that an error of $0'\cdot1$ in I would give an error of approximately 4γ in T at Valentia. In addition, it is to be remembered that the secular change data for Valentia are obtained from absolute observations made at fixed hours at any of which the value obtained for an element may differ, by an amount which is not necessarily constant, from its true mean value for the day of observation. It is by no means improbable that owing to this and errors of observation, uncertainties to the extent of several tenths of a minute of arc may be introduced into the mean value of I for the year. For the average change over a series of years these possible errors are naturally much diminished and the average fall of 33γ per annum in the total force obtained from the values in Table D is probably a close approximation to the true change. This continued decrease in the total force indicates that the rise in the value of the horizontal force observed since 1920 was not a true increase in the magnetic field but merely a component increase arising from the continued fall in the inclination, which becomes proportionally more effective in the horizontal component as the actual inclination angle itself becomes smaller. The magnetic field in the Valentia district continues to become less year by year, therefore, although without observations of inclination the opposite would have appeared to be the case in some recent years.

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 mb. is written 005·6. This rule does not, however, apply to monthly means.

Readings in degrees absolute at exact hours, Greenwich Mean Time.

353. Cahirciveen (Valentia Observatory) : North Wall Screen : h_t (height of thermometer bulbs above ground) = 1·3 metres.

NOTE.—The initial 2 or 3 of the readings is omitted, *i.e.*, 275·0 degrees absolute is written 75·0.

TEMPERATURE: ANNUAL MEANS OF HOURLY VALUES.

From readings in degrees absolute at exact hours, Greenwich Mean Time.

365. Cahirciveen (Valentia Observatory) : North Wall Screen : h_t = 1·3 metres. **1926.**

* Computed from the mean temperatures and the mean relative humidities. † Mean of the column. ‡ Mean of the row.

Percentages at exact hours, Greenwich Mean Time. Determined as explained on page 14.

372. Cahirciveen (Valentia Observatory) : North Wall Screen : h_t (height of thermometer bulbs above ground) = 1·3 metres.

May, 1926.

* Computed from the mean temperatures and the mean relative humidities. † Mean of the column. ‡ Mean of the row.

Percentages at exact hours, Greenwich Mean Time. Determined as explained on page 14.

378. Cahirciveen (Valentia Observatory) : North Wall Screen : h_t (height of thermometer bulbs above ground) = 1·3 metres.

383. Cahirciveen (Valentia Observatory). NOTES ON RAINFALL. **1926.**

Notable Falls of the Year.—There were no remarkably heavy falls of rain during 1926. The heaviest rain was experienced on the 30th August when 22 mm. fell between 1 h. 30m. and 4 h. 25 m.; from 3 h. to 4 h. on this date 11·3 mm. fell, this being the highest hour's fall of the year. 21 mm. was registered between 23 h. on the 2nd, and 4 h. 20 m. on the 3rd January; 7·1 mm. falling between 3 h. and 4 h.

Dry Periods.—The only absolutely dry period of any note was the 13 days from the 25th June to the 7th July, inclusive, when no rain was registered.

Wet Periods.—From the 1st November to the 29th, inclusive, some rain was recorded on every day; on only four of the twenty-nine was the amount less than 1 mm. The first eleven days of January were part of a period of 23 days beginning on the 20th December, 1925, on all of which rain was measured; only two of these days had less than 1 mm. of rain.

Amounts in millimetres for periods of sixty minutes between the exact hours, Greenwich Mean Time.

384. Cahirciveen (Valentia Observatory) : H_r (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + h_r (height of receiving surface above ground) = 9·1 metres + 0·5 metre. **January, 1926.**

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

January, 1926.

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

March, 1926.

G.M.T.	1.		2.		3.		4.		5.		6.		7		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

May, 1926.

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10		11.		Noon.	

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

September, 1926.

13.		14.		15.		16.		17.		18.		19.		20.		21.		22.		23.		24.		Mean	Day.

Direction expressed in degrees from North (E = 90°, S = 180°, W = 270°, N = 360°) : Speed in metres per second.

418. Cahirciveen (Valentia Observatory) : H_a (height of anemograph above M.S.L.) = Height of ground above

Averages for periods of sixty minutes centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 17 metres + 13 metres.

November, 1926.

INTRODUCTION.

The Observatory was built in 1769 as the private observatory of King George III. Since 1842 it has been devoted to physics and meteorology. The meteorological records are continuous from 1854. The Observatory is in the Old Deer Park, Richmond (Surrey), about 10 miles (16 km.) to the west of the City of London. The Observatory stands on a low artificial mound whose level is about 1½ metres higher than that of the surrounding park. The river Thames is distant about 300 metres on the north and west. Kew Gardens, which are extensively wooded, lie to the east-north-east, the nearest point of the Gardens being about 600 metres away. The town of Richmond, to the south-east, is about 1,100 metres distant. On the east side of the Park is the main road from Richmond to Kew; on the south side the railway from Richmond to Twickenham. The Old Deer Park is mainly open pasture. Round the Observatory a golf course has been laid out. Another open area partly wooded, Syon Park, lies to the north-north-east across the river. Richmond Park is about 1½ miles (2½ km.) to the south-east. General views of the Observatory building and the exposure lawn are to be found in the 1923 volume. For the early history of the Observatory reference may be made to papers by S. P. Rigaud (The Observatory 1882, p. 279), R. H. Scott (Royal Society's Proceedings, Vol. 39 (1885), pp. 37-86), C. Chree (The Record of the Royal Society, 1897), and R. S. Whipple (Proceedings of the Optical Convention, 1926).

From the beginning of the year under review, 1926, Galitzin seismographs have been in continuous operation at the Observatory. These instruments, which were provided in 1910 by the generosity of Professor (now Sir Arthur) Schuster, were brought from Eskdalemuir in 1925. Some account of the installation is given on p. 332.

The seismological diary is incorporated in the present volume.

METEOROLOGY.

The elements dealt with in the following tables are: atmospheric pressure, temperature, humidity, rainfall, sunshine, solar radiation, wind speed and direction, earth temperature, minimum temperature on the grass, level of underground water; there is also a diary of cloud and weather.

For brief descriptions of most of the instruments from which values of the above elements have been obtained and of the methods of tabulating the records, reference should be made to the General Introduction (pp. 10-16). The following notes supplement, where necessary, the information contained therein

Notes on Instruments.

Pressure.—The barograph* is mounted in the basement of the Observatory, where the diurnal variation of temperature is very small. The normal position of the instrument has been in the north room occupied by the magnetographs. When the magnetographs were removed and the preparations for the installation of the seismographs were commenced, the barograph was placed in the photographic dark-room (June 16th, 1925). The instrument remained in that position during 1926. The barograph magnifies barometric changes in the ratio 1·553 : 1, i.e., the change of ordinate equivalent to a change of 1 mm. in the height of the barometer is 1·553 mm. "Residual corrections," obtained from the control observations taken daily with the Newman barometer at 9h,15h and 21h, are applied to the hourly measurements. The same correction is applied to all the readings on the same photographic sheet, i.e., generally for forty-eight hours. The individual entries published for the hours of the control observations may differ by ·3 mb. from those observations. The Newman barometer is compared from time to time with the two large mercury barometers, which were set up in 1855 and 1860 respectively and are still recognised as standards. A zero correction is based on these comparisons. The correction + 0·2 mb. (+ ·006 mercury inch) which has been applied for many years, remained in use during 1926. Comparisons are made on the assumption that the value of the acceleration due to gravity is $g = 981{\cdot}199$ cm/sec^2. This is the value given by pendulum observations.† The departure from the value given for the latitude by Helmert's formula is insignificant. On a few occasions when a loss of trace occurred, the missing hourly values were derived from the Dines Float Barograph.* There were 7 hours in the year for which this was necessary.

Temperature and Humidity.—The thermograph is mounted in the West Room on the first floor of the Observatory, the thermometer bulbs being exposed in the screen attached to the north wall of the building. This screen has single louvres and the bottom is open. There is an additional flat louvred screen which shields the main screen from direct sunshine when the sun is in the West and not too low. The height of the bottom of the bulbs of the recording thermometers above the bottom of the sides of the screen containing them is 30 cm. in summer, 33 cm. in winter. The height of the bulbs above the top of the artificial mound on which the Observatory stands is approximately 3 metres; the height above the lawn where the raingauge is situated is approximately 5 metres. The scale values of the photographic records are not identical for the dry and wet-bulb curves. For the dry-bulb, tube No. 4 II. was in use and the scale value was 1 mm. =0·3336a; for the wet-bulb the old Falmouth wet-bulb tube (no number) was in use and the scale value was 1 mm = 0·290a.

The control thermometers, which were graduated and mounted by Messrs. Negretti & Zambra in 1915, had been made and filled many years before and were therefore well seasoned. The National Physical Laboratory certificates dated 1915 give corrections to the nearest 0·05° C., the largest being 0·10°. The thermometers are tested each January in ice. According to tests made in January, 1926, there was no indication of any change of zero. The water for the wet-bulb thermometers used to be supplied from a small open tank inside the screen and it was customary to fill the tank to overflowing several times each day. In November 1925 a tank was fitted outside the screen. A tube leads from this tank to two cups from which

---

* For a description of this instrument see *Observatories' Year Book*, 1923, p. 94.

† A comparison between the values of "g" at Cambridge and Kew Observatory was made during the year 1925 by Sir G. Lenox Conyngham with the assistance of Mr. G. Manley. A similar comparison between Potsdam and Cambridge was made by Prof. Meinesz earlier in the year. These observations are in accord with those made at Kew and Potsdam by Putnam in 1900, from which the value stated above was derived. The value for Potsdam, $g = 981{\cdot}274$, based on the observations of Kühnen and Furtwangler is adopted as the standard of reference.

wicks are taken to the wet-bulbs. A further improvement was made in July, 1926, when a large inverted bottle was set up over the tank. Water flowing from this bottle keeps the level constant in the tank and the cups. The height of the apparatus is adjusted so that water drips slowly from the wet-bulbs. A bottleful of water lasts about a week. It is found that the bottle survives severe frost.

Control eye-readings of the standard thermometers are taken daily at 9h., 15h. and 21h. Residual corrections obtained from the control observations are applied to the hourly measurements of the curves. The same correction is applied to all the readings on the same photographic sheet, i.e. generally for forty-eight hours. The individual entries published for the hours of the control observations may differ by 0·3a from these observations. The larger departures refer to occasions when temperature is oscillating or changing rapidly.

When the wet bulb trace is missing or defective, the missing values are derived from the dry-bulb trace and the records of a hair hygrograph. The same procedure is always adopted when the wet-bulb reading is below 273a. 393 hours had thus to be dealt with during the year. In previous years humidity was determined from the dry and wet-bulb readings by the table based on Glaisher's Factors published in the Computers' Handbook. From the beginning of 1926 the procedure described in the General Introduction to this Volume was adopted.

It may be noted that during 1926, as in previous years, the temperatures published for Kew Observatory in the Daily Weather Report and elsewhere also refer to the North-wall screen. For the daily and weekly reports the readings of maximum and minimum thermometers exposed in that screen are utilised.

Rainfall.—As from January, 1921, the standard raingauge for the Observatory has been an 8-inch gauge with the deep " Snowdon " funnel. The site is level and protected from wind, principally by hedges about 1½m. high and distant 11 metres to East and 17 metres to West. The readings of this standard gauge are at 7h and 18h. The hourly readings of the Beckley gauge are adjusted to give totals in agreement with the standard gauge.

Sunshine.—The sunshine recorder is mounted on the south parapet of the roof. The same frame has been in use since 1880 and it is believed that the ball has not been changed. The ball is now somewhat yellow. The exposure is satisfactory. The greatest elevations of the sky line in the azimuths in which the sun can rise and set are 1° and 3° respectively.

Solar Radiation.—Observations are made with an Ångström pyrheliometer, which measures the intensity of the direct radiation received from the sun by a surface which is normal to the sun's rays. The observations are made within half an hour of noon on all days except Sundays, provided that the sun is visible and not too much obscured by cloud, fog or thick haze. The conditions of the intervening atmosphere are indicated in Tables 493-504 in the column " sky." The amount of radiation is given in milliwatts per square centimetre in the column headed " total." For conversion to the unit more ordinarily employed abroad, the following relation may be used, 1mw. per sq. cm. = 0·01435 gramme-calorie per sq. cm. per minute. The vertical component, i.e. the direct radiation received per square centimetre of a horizontal surface, is also given.

The Ångström instruments in use are by Rose, Stockholm. No. 100 was in use throughout the year. The older instrument No. 24 was kept in reserve. The ammeter is No. 68956, which was certified at the National Physical Laboratory in 1919. The readings are evaluated according to Ångström's original instructions.*

* Report of the International Meteorological Committee, St. Petersburgh, 1899, p. 57.

To bring the readings into accordance with the scale adopted by the Smithsonian Institution, a correction of + 3·5 per cent. is required.*

Wind Speed and Direction.—To the end of 1925 the record of wind velocity was based on the readings from the Robinson-Beckley cup-anemograph. From the beginning of 1926, readings of the Dines tube-anemograph have been used for all the wind data. The vane of the Dines instrument is at the same level as the cups of the other anemograph, 20 metres above the lawn. There are trees in the neighbourhood reaching greater heights. Those along the river to the west of the Observatory and about 280 metres away average 25 metres. The head of the present Dines instrument, set up at the beginning of the year 1923, is of the Mark II pattern. In the vertical tube there are 80 holes in 4 rows of 20. The diameter of each hole is 3 mm. The connecting tubes, 17 metres long, have the internal diameter 12 mm. In June, 1925, it was noticed that the wind speed given by the pressure tube anemograph was rather less than that given by the Robinson cups. Calibration with a pressure gauge shewed that the adjustment of the pressure-tube instrument was not in accordance with the prescribed formula. From September 20th, 1925, a correction of + 0·5 m/s was applied to all readings of the charts from 0·5 m/s upwards (readings 0·1 to 0·4 m/s being doubled). With this correction the differences between the two anemographs were almost eliminated. The correction was in use throughout the year 1926.

Wind direction is given by a twin-lever recorder attached to the vane of the Dines instrument. In accordance with an old convention, wind direction is not printed when the speed of the wind averages less than 1·6 metres per second, though the present vane is sensitive to lighter currents.

Earth Temperature.—The two thermometers in use were at 30 cm. and 122 cm. The ground in which the tubes for the thermometers are sunk is under grass. The soil is gravel. The site is well exposed. There are, however, three fruit trees about 9 metres to the east and 6 metres high. The bulb of the lower thermometer is 430 cm. above sea level. As will be seen from Table 521 the surface of the underground water surpassed this level at the beginning of the year when the park was flooded.

Minimum Temperature on the Grass.—The grass minimum thermometer is set at 18h and read at 9h on the succeeding day, the reading being assigned to the day of reading. The thermometer is placed with the bulb about 25 mm. above the turf. The exposure is good, there being no obstruction within 76° from the zenith. The thermometer in use up to December 22nd was M.O. 23005. The jacket of this thermometer having been broken M.O. 23006 was taken into use. Both these thermometers have spherical bulbs, diameter 17 mm.

Notes on the Meteorological Tables.

The Weather of 1926.—The year was notable for the deficiency in sunshine. The daily mean of sunshine as shown by the Campbell-Stokes sunshine recorder was 3·62 hours, whereas the normal (the average for the years 1881-1915) is 4·04 hours.

Precipitation.—Snow or sleet fell on 8 days, 3 being in January, 3 in March, one in October and one in December. The only snow which lay for a considerable time occurred in January. The ground was covered for five days but the depth did not exceed 6 cm.

Temperature.—There were no unusual extremes of hot or cold weather during the year. The highest temperature recorded (in the north-wall screen) was 302·6a, on July 14th; the lowest 265·2a on January 16th. There were three "ice-days," i.e., days with maximum temperature in the screen below 273a. These were consecutive days, January 14th, 15th, 16th. The warmth of September was unusual, the mean temperature for the month being higher than that of June; indeed the second hottest day of the year was September 19th, with a maximum temperature of 301·7a.

Diurnal Variation of Pressure and Temperature.—Harmonic Analysis. In accordance with the precedent of the last four years, the first harmonic components have been computed for each month. The results are tabulated in Tables A and B.

The inequality is supposed to be given by the expression

$$c_1 \sin (15\, t^\circ + \alpha_1) + c_2 \sin (30\, t^\circ + \alpha_2) + \ldots\ldots$$

t being the time in hours since midnight. The angles α are the phases of the several sine-waves at midnight. The curves are tabulated according to Greenwich mean time but the phases in Table A have been reduced to local mean time. The difference in Longitude between Kew and Greenwich being only 19′ the correction is hardly appreciable in the figures which are rounded to the nearest degree.

Summer	3·487	226	·241	62	·254	26	·060	20

NOTE.—*Winter* comprises the four months January, February, November, December, *Equinox* the months March, April, September, October, and *Summer* May to August.

Level of Underground Water.—In Table 521 there is given for each day the mean height above sea level of the surface of the underground water. The level actually measured is the surface of water in a pipe which passes through the floor of the basement into the ground. The water level depends mainly on the state of the river Thames. The Observatory is close to Richmond lock, which is half-tidal, and the underground water is in summer a little below the level of low water above the lock (220 cm. above M.S.L.). The effects of the spring and neap tides are conspicuous in the fluctuations of level in summer.

Cloud Amount.—The mean cloud amounts for the six hours of observation are given month by month in the diary of cloud and weather. The following means are derived from these data.*

Mean Amount of Cloud from Six Observation Hours.

Month	Jan.	Feb.	Mar.	Apl.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year.
Cloud ...	7·0	8·1	6·9	7·5	7·5	6·5	6·8	6·1	6·4	7·1	7·7	6·7	7·0

Mean Amount of Cloud for the Year at the Six Observation Hours.

Hour ...	7h	9h	13h	15h	18h	21h
Cloud ...	7·2	7·2	7·5	7·7	6·6	5·9

Visibility.—The objects used for the classification of visibility are enumerated below. The Observatory is on very low ground. The view is bounded on the south-east by Richmond Hill and on the west by the trees near the river. For object H a church tower seen through trees and with high ground behind it has to be used. There is no conspicuous object at the appropriate distance to serve as I, and interpolation is necessary. The object J is in London and is therefore more affected by atmospheric pollution than the other objects.

ATMOSPHERIC ELECTRICITY.

The systematic observations in atmospheric electricity are devoted to potential gradient, air-earth current and ionization. In the case of potential gradient there is continuous autographic registration ; the other elements are observed each afternoon when conditions are favourable.

Potential Gradient.—The Kelvin water-dropper electrograph has been housed since 1915 in a low building known as the Clinical House. The pipe carrying the jet projects through a hole in a window and is adjusted so that the point where the jet breaks into spray is 1·50 m.† from the window and 1·73 m. above the pool into which the water falls.‡ The electrogram is a record of the difference of potential between the ground and the point where the jet breaks. The aim is, however, to obtain the potential gradient in the open. For this purpose observations are made at a site in the Observatory garden. The apparatus for these " absolute " observations consists essentially of a long insulated rod carrying at the end a lighted fuse, which is connected to an electrostatic voltmeter. Readings are taken with the fuse at one metre and at two metres above the ground, the grass on which is kept short. The observations are taken about noon on all convenient dry days. From the observations the ratio of the potential gradient in the garden to the potential recorded by the electrograph is computed. Such a ratio is given for each month in Table 535.

In the spring of 1924 there was a change in the surroundings of the site on the lawn where observations are taken ; previously there had been fruit bushes and vegetables on either side of the grass plot. The ground was dug up in the spring and grass was sown in May, 1924. There is no indication in the run of the exposure factors that this had any effect.

There was, however, a notable change in the ratio between August and October, 1924. This change persisted, the average value of the ratio, which had been 2·15 in 1923, rose to 2·77 in 1925. It was shown eventually that the change could be accounted for by the erection in September, 1924, of an aerial for the reception of time-signals by wireless telegraphy. This affected the exposure of the electrograph but not that of the apparatus for absolute observations. There is therefore no reason to suspect the computed potential gradient values. The aerial was removed on the 31st August, 1926, and the mean exposure factor for the remaining months of the year was reduced to 2·10 ; for all practical purposes the same as before the erection of the aerial.

During the year§ two electrostatic voltmeters, No. 1684 and No. 1685, were used for the absolute observations. The voltmeters and also the electrograph are calibrated at frequent intervals by means of a Cambridge and Paul potentiometer, a high tension dry battery being used as a source of potential difference. The battery in use in 1925, showed signs of marked deterioration towards the end of the year. It was replaced early in 1926.

The data appearing in Table 534 include the electrical character figure assigned to each day from the consideration of the electrograms. Of the character figures, 0 denotes the absence of negative potential, 1 implies the existence of negative potential at one or more times during the day but with a total duration of less than 3 hours,

---

† This measurement was made in July, 1926. It is believed that there has been no appreciable change since 1915.

‡ This height is regulated and has been kept the same.

§ As from January 1st, 1923, the electrostatic voltmeters took the place of the Kelvin portable electrometer, No. 81, previously used for this purpose.

while 2 implies the existence of negative potential with a total duration exceeding 3 hours. As a negative potential gradient hardly ever occurs except when rain is in the neighbourhood, character 0 occurs on dry days and character 2 on days with continuous rainfall. The mean character figure for 1926 was 0·64, slightly bigger than that for 1925, and therefore appreciably above the average for the previous 15 years, 0·609.

Table 535 gives daily data derived from measurements of the electrograms. They represent means for 60-minute intervals centred at the exact hours 3h, 9h, 15h, and 21h G.M.T. Blanks indicate that the trace was in some way defective. On some occasions the curve, though existent, is so oscillatory that no satisfactory estimate is possible of the mean value of the ordinate. Such occasions are indicated by the letter *z*. If there is no doubt as to the sign of the hourly mean value, though a numerical measure is unobtainable, the sign is indicated by a + or a − attached to the *z*. The symbol *z* ± indicates that there were oscillations on both sides of the zero line, and that the sign of the mean value was uncertain.

The extreme hourly mean values in Table 535 are + 1005 v/m at 3h on November 28th and −880 v/m at 3h on January 19th. The former value is representative of foggy conditions; on this particular occasion the fog developed about midnight, when an easterly wind sprang up following a period of 14 hours of light indefinite wind. The easterly wind persisted throughout the 28th with a high potential gradient all day. The extreme negative potential gradient of January 19th was associated with light rain. The potential gradient was persistently negative and free from large oscillations from 22h on the 18th to 6h on the 19th, during which time light rain or drizzle was falling continuously.

Of the two sets of mean monthly values at 3h, 9h, 15h and 21h given in Table 535 at the foot of each month's data, the first set (*a*) represents the arithmetic means of all the positive potentials in the column, the second set (*b*) represents the algebraic mean derived from all days on which all four hours were represented. The last line gives the mean value for each month as derived from the (*a*) and the (*b*) values respectively.

For reasons explained in the 1922 Year Book, it is believed that the values (*a*) may be expected to give approximately the true monthly mean from all days when negative potentials are excluded, while the values (*b*) may be expected to give approximately the true monthly mean when negative potentials are included. But a reservation is necessary in both cases, for the highly oscillatory occasions such as are met with during thunderstorms have been omitted, and this omission may have a sensible effect.

If the monthly means in Tables 535 and 536 be compared, it will be found that the quiet day mean is the higher in eight months out of the twelve. In some of the eight months its excess over the mean (*a*)—which generally exceeds the mean (*b*)—is considerable. For the year, as a whole, allowing equal weight to the 12 months, the quiet day mean, the mean (*a*), and the mean (*b*) are respectively 279 v/m, 274 v/m and 260 v/m. In each case the values are much smaller than those for 1925, which were 326 v/m, 301 v/m and 283 v/m.

As to comparison with earlier years it is to be noted that the present method of making the "absolute" observations was initiated at the beginning of 1910. Since then there has been no considerable change in the exposure at the control station. The annual mean potential gradient for selected quiet days is available from that date onwards.*

* Estimates for the years 1898–1909 are given by Chree, *Phil. Trans.* A (1915) p. 141. The change of site of the electrograph in 1915 is discussed in *Hourly Values*, 1916.

1910	310 v/m	1916	367 v/m	1922	318 v/m
11	301 v/m	17	354 v/m	23	318 v/m
12	300 v/m	18	346 v/m	24	329 v/m
13	335 v/m	19	331 v/m	25	326 v/m
14	345 v/m	20	315 v/m	26	279 v/m
15	354 v/m	21	281 v/m		

The average for the 17 years is 324 volts per metre.

The mean for 1926 is a minimum. Along with the low value for 1921 it was probably to be attributed in part to the exceptional atmospheric conditions prevailing during the coal strikes of those years. Apart from these abnormalities a smooth change of potential gradient is to be noticed. In fact, the figures have been quoted* by Dr. Bauer as evidence for a connection between atmospheric electricity and solar activity.

The diurnal inequalities and the mean monthly and annual values in Table 536 are based on the curves of quiet days selected from those entirely free from negative potential. Other objects aimed at in the selection of the days are freedom from large irregular movements, absence of indications of inferior insulation in the electrograph, and the avoidance, so far as possible, of large non-cyclic changes. The quiet days numbered 10 in each month ; but to complete that number in May and November it was necessary to include several 24-hour periods which did not commence at midnight.

Except in these cases the non-cyclic change is given explicitly in Table 536, so that anyone who may desire to reproduce the figures as they were before the non-cyclic correction was applied can easily do so.

All the inequalities show a well marked double oscillation with minima in the early morning and early afternoon, maxima in the late morning as well as in the evening. The diurnal inequality for the whole year shows the higher maximum at 20h, the lower minimum at 4h. This is not the case in every year. The hours of the extremes and the range of the inequality is given for each year from 1910 in the following list.

Year.	Max. hr.	Min. hr.	Range v/m	Year	Max. hr.	Min. hr.	Range v/m	Year.	Max. hr.	Min. hr.	Range v/m
1910	20	4	138	1916	20	4	151	1922	20	4	144
1911	9	4	154	1917	20	4	154	1923	9	4	160
1912	9	4	149	1918	20	2	139	1924	20	4	133
1913	19	3, 4	160	1919	8	4	124	1925	19	3	129
1914	20	3	169	1920	9	3	122	1926	20	4	118
1915	19	5	173	1921	20	3, 4	132				

It will be seen that the range has been considerably lower in most recent years than it was in the years 1911 to 1917.

If the inequalities for the year and the seasons are compared with the corresponding inequalities for atmospheric pollution given in Table 538, the remarkably close similarity in the hours of occurrence of the principal maxima and minima noted in previous years is not borne out. There is, however, the same marked double oscillation throughout the day in both elements, a principal maximum or minimum of one falling at the same time as the secondary maximum or minimum of the other. In this connection it should be borne in mind that 1926 was an abnormal year on account of the prolonged coal strike and also that the same days have not been used in obtaining these inequalities.

* **Washington**, Carnegie Institution. Researches of the Dept. of Terr. Mag., Vol. V., pp. 361–384.

Air-earth Current.—To determine the current flowing from air to earth, the conductivity of the atmosphere at one metre above the ground is measured by means of the Wilson universal electrometer.* For calculating the conductivity at 15h, four observations, each giving the leakage from a charged plate in 5 minutes, are averaged. The product of the conductivity so determined and the potential gradient at 15h (as given in Table 535) is taken as the measure of the air-earth current. The conductivity is not observed during rain nor when the potential gradient is negative. Data are available for about two-fifths of the days of the year 1926.

The conditions under which the air-earth current is measured are maintained as uniform as possible, but they differ from the conditions under which the vertical current passes from the air to the earth in the absence of the apparatus. The presumption is that the results obtained would require to be multiplied by a factor to represent the true air-earth current. The monthly mean of the observed values of the current varied from 0·42 in January to 1·00 in September in terms of the unit 1×10^{-16} ampere per square centimetre. Allowing equal weight to each month we find that the mean for the year in terms of the above unit is 0·71. The mean derived directly from the 144 observations is also 0·71. There is very little difference from the corresponding values for other years.

There is some doubt as to the comparability of observations made with the Wilson apparatus and other estimates of the air-earth current. Determinations based on separate measurements of the conductivity for positive and negative electricity have yielded on the continent averages about 2×10^{-16} amperes per square centimetre.

Ionic Charges.—Table 534 also gives the volume-charges carried by such positive and negative ions (including all of the more mobile type) as are caught by the Ebert apparatus.† The observations extend over some 20 minutes near 15h, being simultaneous with the experiments with the Wilson electrometer.

Normally, two Ebert instruments are in use, one charged positively, the other negatively, the signs alternating from day to day.

From the beginning of the year to the middle of March both instruments were in use. No. 2965 was then sent to the makers for new fibres and No. 3327 was used alone for the remainder of the year. During the months when only one instrument was available, observations of positive and negative ionization were made on alternate occasions.

In interpreting the observations it is to be borne in mind that even in pure mountain air the greater part of the electric charge is carried by the sluggish "Langevin" ions. In less pure air a still higher proportion of the ions is immobilised and there is a decrease in the number of the small ions, i.e., of ions such as are caught by the Ebert apparatus and are effective in producing the conductivity of the atmosphere.

As is usual at Kew the highest values of the measured ionization occurred during the summer half of the year. Positive ionization exceeding 1×10^{-16} coulomb per c.c. occurred on days in June and August. The negative ionization exceeded the same limit on June 22nd. In foggy weather the number of small ions is very small and uncertain. The lowest ionization tabulated occurred on April 13th and October 26th being $+0{\cdot}09$ and $-0{\cdot}09 \times 10^{-16}$ coulomb per c.c. on the two days respectively. The averages for the year were $+\,{\cdot}53$ and $-\,{\cdot}41 \times 10^{-16}$ coulomb per c.c. According to Millikan's experiments‡ the ionic charge is $15{\cdot}9 \times 10^{-20}$ coulomb, so that these averages correspond respectively with 330 positive and 260 negative ions per c.c. These averages are much lower than those obtained by observers in other countries. According to Bauer and Swann§ the means for the principal observations reported at land stations before 1917 were 737 positive and 668 negative ions per c.c.

ATMOSPHERIC POLLUTION.

The Owens atmospheric pollution recorder or air filter No. 1* is normally situated in the Clinical House, and the air it samples is about $1\frac{1}{2}$m. above that of the adjacent ground. From January 1st to July 17th it was housed in the "clock room," the air being drawn into the instrument from a point outside at the same level as at the original site. The weight of the pollution is not obtained directly, but is deduced from shade numbers 0, 1, 2, etc., assigned to the deposit left on filter paper through which a measured volume of air has been drawn. Shade number 1 answers to 0·32 milligrams per cubic metre, according to Mr. J. G. Clark's determinations.†

Table 537 gives mean hourly values derived from all the days of the month for which complete records were obtained. There were 339 such days in the year. The highest and lowest of these hourly values are in heavy type.

Table 538 gives diurnal inequalities derived from the data in Table 537 after the application of non-cyclic corrections. The principal reason for computing the diurnal inequalities was to facilitate comparison with the corresponding diurnal variations in barometric pressure and the potential gradient of atmospheric electricity.

Record was entirely lacking for two days, and for the greater part of a good many other days it was deficient owing to defective behaviour of the apparatus. Of the days of complete record November 25th was the dirtiest, the mean amount of pollution from the hourly values being 1·3 milligrams per cubic metre. The day was foggy throughout, the fog forming in the evening of the previous day and not clearing until noon on the following day. The fog became very dense in the late evening of the 25th, and the pollution attained a maximum value of 3·2 milligrams per cubic metre at 23h. This was the highest hourly value in the year, but was also attained at midnight on January 11th.

Owing, no doubt, to the prolonged coal strike of 1926 the atmosphere was considerably clearer than in any previous year recorded. All the months of 1926, except April, were much cleaner than those of 1925.

Allowing equal weight to each month the mean value computed for the year 1926 was ·20 milligrams per cubic metre, as compared with ·26 in 1925, ·32 in 1924, ·31 in 1923, ·39 in 1922 and ·31 in 1921. In any discussion of these mean values it should be borne in mind that at Kew Observatory the great majority of estimates are shade 0 or shade 1. To discriminate between these two shades is difficult and the decision depends on the "personal equation" of the observer. Some change in standard from year to year is inevitable.

The nature of the diurnal variation is most easily recognised in Table 538. There is always a well defined minimum during the night and another in the early afternoon. The first maximum of the day usually occurs about 9h and the second one follows about 12 hours later. This double oscillation is apparently due to two causes, the variation in human activity in producing pollution and the variation in the wind which disperses it. In summer the principal maximum is in the forenoon, the principal minimum in the early afternoon. In general, in winter, on the other hand, the greatest pollution is recorded in the evening, the least in the early hours of the morning. Compared with previous years 1926 was exceptional (probably on account of the coal strike), and, in the year, all seasons and all months except November and December the principal maximum occurred in the forenoon.

* A description of the instrument is given in the *Report of the Advisory Committee for Atmospheric Pollution.* 4th Report, 1917–1918 (p. 20).

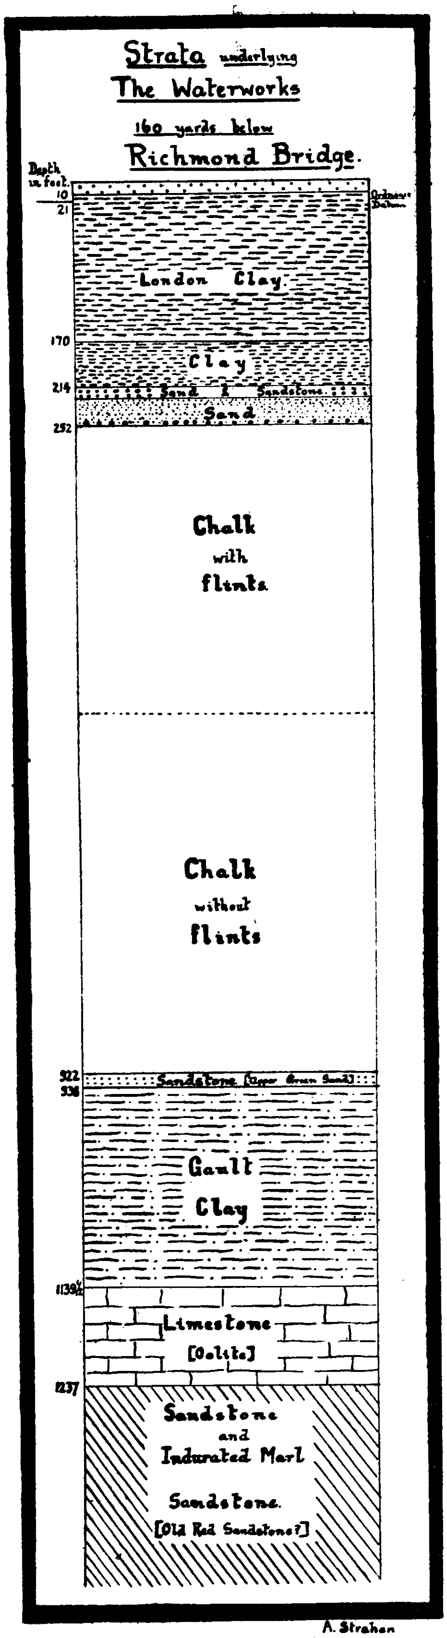
SEISMOLOGY.



A. Strahan
Prof. Paper No. 10, Survey of India.

Notes on Instruments.—The instruments which were transferred from Eskdalemuir Observatory during the latter part of 1925 have been in regular operation since the beginning of 1926. They consist of three Galitzin pendulums, with galvanometric registration arranged to record earth displacements in the north, east and vertical directions. The installation is situated in the basement rooms of the Observatory building, the pendulums being placed on a massive concrete pillar, separated from the floor, in the old magnetograph room. The galvanometers and recording apparatus are accommodated on slate slabs in the old seismograph room, which housed the Milne instrument until it was put out of action on June 17th, 1925. In order to eliminate temperature variation as far as possible, the windows of the pendulum room are provided with triple glass and also shielded by louvred screens from direct sunshine which might fall on them morning and evening. The annual range of temperature variation is about 10° C. and the mean daily range about 0·2° C.

The concrete pillar rests on gravel. The underlying geological strata are shown in the diagram on this page. The diagram is based on the results obtained* in sinking a well near Richmond Bridge. The Richmond boring terminated at a depth of 440 metres in Old Red Sandstone. At Stonebridge Park, 8 km. to the north, a boring was carried down† to a depth of 600 metres, the last 280 metres being in Old Red Sandstone. There is no information as to deeper strata near Richmond. It may be noted, however, that the sandstone beds dip at about 30° and that a boring at Little Missenden, Bucks, entered Silurian rocks at a depth of 370 metres with no evidence of the presence of Old Red Sandstone.

For detailed description of the Galitzin seismograph and for particulars of interpretation of the records, reference may be made to Fürst B. Galitzin's "Vorlesungen über Seismometrie" (Leipzig, 1914), or to G. W. Walker's "Modern Seismology" (London, 1913).

Timing is controlled by a half-seconds clock (Morrison 8587) which is rated daily by comparison with the Greenwich wireless time-signal relayed from Daventry. Time breaks are made electro-magnetically every minute and seismometric readings can be determined to the nearest second.

Frequent adjustments of the pendulums were made during the year in order to bring the constants as near as possible to the optimum values, and in most cases standardisation tests were done soon after readjustments. The standardisation of the vertical instrument presents great difficulty and for several months no reliable values for the constants were available. The free periods of the galvanometers (T_1), were determined in November, 1925, and were found to have suffered very little change since the original determinations at Eskdalemuir were made. The lengths of the simple equivalent pendulums (l), are assumed to have remained unaltered. These constants are as follows :—

	N	E	Z
T_1	24·68 sec.	24·80 sec.	13·04 sec
l	118 mm.	118 mm.	360 mm.

N, E, and Z indicate the north, east and vertical components respectively.

The table given below summarises the values of the other constants obtained from the standardisation tests. T is the free period of the pendulum, μ is a damping co-efficient which vanishes when the free movement of the pendulum is just aperiodic, A is the length of the beam of light from the galvanometer mirror to the recording drum (usually about 1100 mm.), and k is the "transmission" factor. The quantity $\frac{kA}{\pi l}$ may be regarded as a relative measure of the nominal magnification. A more detailed explanation of the meaning of these constants is given in the works referred to above.

† Records of London Wells, Mem. Geol. Survey 1913.

1926.	Component.	T (sec.)	μ^2	$\frac{kA}{\pi l}$ (sec.$^{-1}$)
Jan. 1 to Feb. 22	N	22·97	+0·162	69·7
Jan. 1 to Feb. 22	E	26·12	−0·131	103·7
Feb. 22 to Apr. 22	N	22·45	+0·127	67·4
Apr. 22 to May 27	N	24·02	−0·214	62·4
Mar. 4 to May 27	E	27·75	−0·026	26·7
May 27 to Aug. 30	N	25·33	−0·128	59·9
May 27 to Aug. 30	E	22·66	+0·347	42·8
Aug. 30 to Nov. 1	N	23·89	+0·199	66·5
Aug. 30 to Nov. 1	E	23·46	+0·351	41·8
Sep. 3 to Nov. 4	Z	12·11	+0·213	198
Nov. 1 to Dec. 31	N	23·45	+0·102	47·6
Nov. 2 to Dec. 31	E	23·31	−0·052	43·5
Nov. 4 to Dec. 31	Z	10·82	−0·220	113·9

The expression used for the determination of the scale value was :—

$$\text{Magnification of record} = \frac{kAT_p}{\pi l} \cdot \frac{1}{(1+u^2)(1+u_1^2)\sqrt{1-\mu^2 f(u)}}$$

Where T_p is the period of the earthwave considered, $u = \frac{T_p}{T}$, $u_1 = \frac{T_p}{T_1}$ and $f(u) = \left[\frac{2u}{1+u^2}\right]^2$

The Galitzin vertical pendulum is particularly sensitive to temperature changes, and frequent adjustments of the pendulum are necessary. For this reason the records of this instrument are regarded as only qualitative in certain respects. At the same time it must be noted that the vertical record is an important factor in the determination of an epicentre from the records of an earthquake at a single station.

In windy weather the seismographs, especially the horizontal components, are affected by slow oscillations, which are attributed to the tilting of the ground, the movement being conveyed through the foundations of the Observatory. On occasions the reading of an earthquake record is rendered very difficult, if not impossible, by these irregular disturbances.

Notes on Tables.—The Seismological Diary, Table 539, contains the particulars of the earthquakes recorded at the Observatory. The notation employed is as follows :—

P is the time of arrival of the first phase (longitudinal waves). S is the time of arrival of the second phase (transverse waves). L is the time of arrival of the long waves (surface waves).

i is the sudden commencement of a phase. *e* means a gradual or indistinct commencement of a phase. F is the end.

The suffixes N, E, Z indicate that the estimates refer to the records from the north-south, east-west and vertical seismographs respectively.

PR_1, PR_2 . . . are longitudinal waves reflected once, twice . . . at the earth's surface, prior to their arrival at the station. SR_1, SR_2 . . . similarly denote reflected transverse waves. Any times given for reflected waves refer to the beginning of a disturbance at the Observatory.

M_1, M_2 . . . are the estimated times of successive maxima of the amplitude of oscillation of the ground. These are derived from the times of the displacements shown on the records by the application of the corrections given in Galitzin's work referred to above.

The period is the duration of a double oscillation (to and fro movement).

A_N, A_E are the amplitudes, in microns (μ=0·001 mm.), of the components of the true displacement of the ground from the position of rest. Displacements to the north and east are regarded as being positive and in these cases no sign is given. For a displacement to the south or west, a negative sign (−) is used. When successive positive and negative displacements have the same magnitude the time of occurrence is given for the positive one. (Owing to uncertainty as to the constants of the vertical seismograph, values of A_z are not given.)

Δ is the distance in kilometres of the epicentre measured along the arc of the great circle passing through the station. This distance is derived from the interval between P and S, by Klotz's "Seismological Tables" (Publication of the Dominion Observatory, Ottawa, Vol. III, No. 2). The azimuth of the epicentre (0° to 360°) is measured from north through east. When an estimation of the azimuth is possible, it is used, together with Δ, to determine the co-ordinates of the epicentre. In other cases where co-ordinates are given, the information has been obtained from other sources (usually Strasbourg or Oxford), and the origin of the determination is inserted in brackets.

Brackets enclosing figures or phase symbols indicate that the information is uncertain.

The total number of shocks recorded during the year was 306. The phases being sufficiently well defined, estimates of the epicentral distance were obtained for 55 shocks. There were ten earthquakes which produced a disturbance at the Observatory with an amplitude exceeding 0·1 mm. in a horizontal component. These earthquakes originated in the Solomon Islands (January 25th and April 12th), in Costa Rica (February 8th), in Anatolia (March 18th), near Crete (June 26th, August 30th and September 19th), near Java (September 10th), south west of New Zealand (October 3rd), and in New Guinea (October 26th).

Two near earthquakes were recorded, one in Jersey (July 30th), and the other near Leominster (August 15th). A detailed analysis of the records of these disturbances has been made by Dr. Harold Jeffreys ("On Two British Earthquakes," Monthly Notices of the Royal Astronomical Society, Geophysical Supplement, Vol. I, No. 9).

Microseisms.—In Table 540 are given the amplitude (A) and period (T_p) of the microseisms shown by the north component seismograph on each day at 0h, 6h, 12h, and 18h. The group of waves of greatest amplitude occurring in the 30 minutes centering at the hour in question is selected, and the amplitude tabulated is the mean obtained from two or three waves in that group. The period is derived from a measurement made on the same group. In computing the mean period occasions of zero amplitude are omitted.

The mean values of amplitude and period for each month of 1926 and for the year, together with the means obtained at Eskdalemuir for the years 1911-1924 are given below:—

MICROSEISMS.—MONTHLY AND ANNUAL MEANS.

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Year.
Richmond— 1926 Amplitude (μ)	2·3	1·7	1·8	1·1	0·5	0·4	0·5	0·6	0·5	0·8	1·7	1·6	1·1

NOTE.—When pressure exceeds 1000 mb. the leading figure 1 is not printed, *i.e.*, 1005·6 is written 005·6. This rule does not, however apply to monthly means.

Readings in degrees absolute at exact hours, Greenwich Mean Time.

450. Richmond (Kew Observatory) : North Wall Screen : h_t (height of thermometer bulb above the ground) = 3·0 metres.

January, 1926.

NOTE.—The initial 2 or 3 of the readings is omitted, *i.e.*, 275·0 degrees absolute is written 75·0.

TEMPERATURE: ANNUAL MEANS OF HOURLY VALUES.

From readings in degrees absolute at exact hours, Greenwich Mean Time.

462. Richmond (Kew Observatory) : North Wall Screen : $h_t = 3{\cdot}0$ metres. **1926.**

* Computed from the mean temperature and mean relative humidity. † Mean of the column. ‡ Mean of the row.

Percentages at exact hours, Greenwich Mean Time. Determined as explained on page 14.

473. Richmond (Kew Observatory) : North Wall Screen : h_t (height of thermometer bulbs above the ground) = 3·0 metres.

480. Richmond (Kew Observatory). NOTES ON RAINFALL. **1926.**

Dry Periods.

The driest period of the year occurred in March. Only 2 days had precipitation exceeding 1 millimetre and there were 20 consecutive days, 7th to 26th, when no rain fell. December was also dry, the precipitation exceeding 1 millimetre on only 2 days. Another spell of 15 days without rain occurred between September 9th and 23rd.

Wet Periods.

Rain fell on every day from January 27th to February 7th (12 days). There was a spell of wet weather in November which persisted, except for a break of 1 day, for 18 days and included falls of 23·7 millimetres and 21·3 millimetres. The total of 130 millimetres is the highest on record for November. The maximum fall recorded for any one day was 27·9 millimetres on June 2nd.

Rainfall Duration.

There were 69 calendar days on which the duration of rainfall was registered as 0·1 to 1·0 hours, 30 days with 1·1 to 2·0 hours, 49 days with 2·1 to 6·0 hours, 20 days with 6·1 to 12·0 hours, and 2 days with more than 12 hours. The days with the greatest duration were June 2nd and November 29th, when the duration was 20·5 hours and 12·8 hours respectively.

Continuous Falls.

On June 2nd it rained continuously for 20·5 hours.

Heavy Falls in Short Periods.

The most outstanding fall occurred on September 24th when 5 millimetres fell in 15 minutes. Other instances of falls of 5 millimetres in an hour or less were on January 7th (5 mm. in 24 mins., 10 mm. in 1 hour 42 mins.), April 25th (5 mm. in 54 mins., 10 mm. in 2 hours 24 mins.), May 14th (5 mm. in 42 mins., 10 mm. in 1 hour 36 mins.), June 18th (5 mm. in 1 hour, 10 mm. in 6 hours), November 8th (5 mm. in 54 mins., 10 mm. in 3 hours) and November 13th (5 mm. in 48 mins., 10 mm. in 2 hours 42 mins.).

Amounts, in millimetres, for periods of sixty minutes between the exact hours, Greenwich Mean Time.

481. Richmond (Kew Observatory) : H_r (height of receiving surface above M.S.L.) = H (height of station above M.S.L.) + h_r (height of receiving surface above ground) = 5·5 metres + 0·53 metres. **January, 1926.**

G.M.T.	1,		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 5 metres + 20 metres.

January, 1926.

G.M.T.	1.		2.		3.		4.		5.		6.		7.		8.		9.		10.		11.		Noon.	

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 5 metres + 20 metres.

March, 1926.

Averages for periods of sixty minutes, centred at the exact hours, Greenwich Mean Time.

M.S.L. + h_a (height of anemograph above ground) = 5 metres + 20 metres.

November, 1926.

Mean for day	(a) 274		(b) 250		(a) 233		(b) 242		(a) 169		(b) 147	

Note.—The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used :—z + Indeterminate, positive value ; z —Indeterminate, negative value ; z ± Indeterminate in magnitude and sign.

(a) Mean from all positive readings.

(b) Mean from all complete days using both positive and negative readings.

Mean Values for periods of sixty minutes, centered at the exact hours, Greenwich Mean Time.

535. Richmond (Kew Observatory). **1926.**

(a) Mean from all positive readings.
(b) Mean from all complete days, using both positive and negative readings.
NOTE.—The Potential Gradient is reckoned as positive if the potential increases upwards. For indeterminate potential gradient the following notation is used: *z* + Indeterminate positive value; *z* — Indeterminate, negative value; *z* ± Indeterminate in magnitude and sign.

The departures from the mean of the day are adjusted for non-cyclic change.

SELECTED QUIET DAYS.

Oxford	51° 46′ N.	1° 15′ W.	61 metres.

INTRODUCTION.

Notes on the tables of Upper Air Temperatures obtained from soundings with registering balloons at Richmond, Sealand and Oxford. 1926.

The tables are presented in the same form as those appearing in the Observatories Year Book for 1925. The Dines pattern meteorograph was employed solely as before, about half of the instruments having been constructed in the Observatory workshop, supplemented by an equal number purchased from outside contractors.

The method of operation remained substantially the same as that described in the Computer's Handbook.*

In the computation of pressure-height a value of gravity constant with height has been assumed, and equal to 981·2; the effect of humidity on the density of the air has been neglected.

A total of 44 soundings were made during the year, 28 from the Distributive Station of the Meteorological Office at Sealand Aerodrome, 15 from Kew Observatory and one from Oxford. Of these 31 instruments were found and returned. The choice of station from which a sounding was made was generally determined in view of the probable direction and length of the run of the balloon. The average height reached was again appreciably greater than in the previous year.

In general the mean of the records on the ascent and descent was employed in computing the published figures. In three cases over the lowest kilometre or two what was judged to be the record of the ascent only was used, the fact being stated in the notes. Except in the cases of soundings made near mid-day in summer, and near the top of some other high daylight soundings, the difference between the two records did not in general exceed 4a., with a mean of about half that value. Whenever direct evidence could be obtained it was almost always found that in the troposphere the descending record was the colder of the two. The reason is believed to lie partly in a temperature lag of the thermograph member, and in daylight soundings also to differential solar heating of the instrument, as between the ascent when the ventilation is comparatively weak, and the descent when it is much more vigorous. In the case of high soundings made during the daytime a pronounced rise of temperature was sometimes observed over about a kilometre at the extreme top, particularly so on the record of the descent immediately after the bursting of the balloon. There is good evidence that this is a fictitious effect due to solar radiation and that the ascent is a great deal more affected by it than the descent. The rise of temperature has accordingly been ignored, and in addition greater weight has been given to the descent than to the ascent in the upper parts of such records as show an unusually large difference between them.

The ventilation of the meteorograph is effected solely by the natural draught produced by its vertical velocity. The coned case referred to last year was employed almost entirely in 1926. The vertical velocity of the rising balloon was of the order 220 metres per minute in about one third of the soundings, and 330 metres per minute in the remainder. After the balloon had burst the instrument fell at the rate of about 700 metres per minute.

* MO. 223, Section II, Sub-section II.

The figures given in the table of lapse rates do not in every case agree with the temperatures appearing in the table of temperature-heights. The reason of this is that both were determined independently from the original data, which can sometimes profitably be read to ·5 degree, and then rounded off to the nearest whole degree.

The lapse rates given between ground level and 0·5 kms. are determined from the reading in the thermometer screen at the station and that of the meteorograph at 0·5 kms. A source of error arises here in that it is not possible to ensure absolute agreement between these two standards, and a small difference is capable of making an appreciable error in the lapse rate. It is possible that lapse rates apparently greater than 10a. per km. in this layer are sometimes due to this cause.

All new meteorographs, and all old ones used again after repair, were seasoned in a vacuum chamber before use by being subjected to several slow reductions of pressure. This process has been found to reduce greatly the chance of a systematic difference occurring between the results of a fast and a slow calibration. More detail is given in the Introduction to the tables for 1923, and within the limits of accuracy at present attainable in the measurement of upper air pressures, the results of the fast reduction of pressure in the calibration test may be taken as applying to the slow reduction in an actual sounding.

The lag, or difference in pressure reading as between a falling and a rising pressure, is of the order 3 or 4 millibars on the average in the middle region of a high sounding, falling off to lesser values on either side. If a correction be applied to the recorded temperature-pressures to allow for this error, it results for an average sounding in the troposphere in an increase in the difference between the temperatures recorded at any pressure on the ascent and descent.

The effect is to make the recorded temperatures on the descent too high by about half a degree at a height of 6 or 7 kilometres, with a tendency for the error to fall off above and below. When the mean of the two records is employed the resultant error is halved and becomes negligible.

During the latter part of the year a hair hygrometer was occasionally fitted to the meteorograph. In such cases only one record of humidity (in general that of the ascent) has been published. The attachment shows changes in relative humidity in the lower part of the troposphere very well, but the absolute value of its readings may be subject to an uncertain error of five or more on the percentage scale. Below a temperature of 250a. it seems very doubtful if the record has any meaning.

In Table 541 occur the entries "Type of Tropopause" and "H_c =Height of Tropopause." These are defined as follows :—Type I. The stratosphere commences with an inversion, and H_c is the height of the first point of zero temperature gradient. Type II. The stratosphere begins with an abrupt transition to a temperature gradient below 2a. per kilometre without inversion, and H_c is the height of the abrupt transition. Type III. There is no abrupt change of temperature gradient, and the base of the stratosphere is taken at the point where the mean fall of temperature for the kilometre next above is 2a. or less, provided that it does not exceed 2a. for any subsequent kilometre. In Table 542 the pressure distribution is classified according to the types defined in "Aids to Forecasting."†

542. **1926.**

NOTES ON PREVAILING WEATHER CONDITIONS AT TIME OF ASCENTS, 1926.

No. of Ascent.	Date.	Time.	
586.	Jan. 11th.	17·20 G.M.T.	Weather fine and mild. Ci-St. 1/10. Suggestion of slight inversion, ground to 0·4 km. on up-trace. Inversion on both traces 1·02 km. to 1·15 km., Temp. 277·5 a. to 278·5 a. Isothermal patches on down trace only 1·62 km. to 1·99 km., Temp. 268 a., and a small patch about 6·45 km., Temp. 246 a. Pressure distribution. Type VI a. (becoming VII c. in the course of the next 36 hours). Intense North-European high centred over Esthonia, low over Atlantic from Azores to Iceland. Light southerly winds over England.
587.	Jan. 12th.	17·07 ,,	Weather fine and hazy. No cloud. Numerous isothermal layers on both traces. Isothermal 0·69 km. to 0·83 km., Temp. 272·5 a. Inversion 0·83 km. to 0·97 km., Temp. 272·5 a. to 273·5 a. Isothermal 0·97 km. to 1·20 km., Temp 273·5 a. Inversion 1·20 km. to 1·42 km., Temp. 273·5 a. to 275 a. Isothermal 1·42 km. to 1·66 km., Temp 275 a. Isothermal 2·52 km. to 2·79 km., Temp. 271·5 a.; 3·67 km. to 3·79 km., Temp. 266 a.; 4·40 km. to 4·56 km., Temp. 261·5 a.; and a high layer, 11·40 km. to 11·55 km., Temp. 208·5 a. (Tropopause 12·5 km.). Pressure distribution. Type VIIc. Intense North-European high centred over Leningrad. Low off Portugal and Mediterranean, and to NW of Iceland. Cold easterly winds setting in over eastern England, but SE winds still quite mild over western districts.
590.	Jan. 15th.	8·20 ,,	Weather overcast, frosty. Small inversion on up-trace 0·23 km. to 0·31 km., Temp. 270·7 a. to 271 a. Small isothermal layer on down-trace 0·84 km. to 0·90 km., Temp. 267 a. Isothermal layers 2·81 km. to 3·20 km., Temp. 254·5 a. and 5·75 km. to 6·17 km., Temp. 234·5 a. Tropopause at 8·1 km. with slight lapse-rate above. Pressure distribution. Type XIII. High over Russia, low over western Europe and Mediterranean. High over Atlantic. Series of small lows over E. England.
591.	Jan. 16th.	8·30 ,,	Weather overcast, mist and hard frost. Isothermal layer on the down trace 0·3 km. to 0·55 km., Temp. 268·2 a. Inversion, mean, 1·55 km. to 2·24 km., Temp. 262 a. to 264·5 a. Small isothermal layer 3·33 km. to 3·46 km., Temp. 260·5 a. Isothermal layer 8·20 km. to 8·50 km., Temp. 224·5 a. Tropopause at 9·3 km. again with slight lapse-rate above. Pressure distribution. Type doubtful. High over north Russia and Azores, low over Germany and western Europe with several centres. Large Atlantic low approaching. Light easterly breezes over England.
595.	Feb. 6th.	11·20 ,,	Weather cloudy, cloud increasing; very mild. Cloud St-Cu. 3/10, A-Cu. 1/10, and Ci. and Ci-St. 4/10. St-Cu from S; A-Cu. doubtful and Ci. from S at 18 radians per hour. Isothermal layers on up trace 0·95 km. to 1·40 km. Temp. 281 a. Inversion 0·88 km. to 0·95 km., Temp. 279·5 a. to 281 a. Latter shown on down trace 0·71 to 0·91 km., Temp. 280 a. to 282·5 a. Pressure distribution. Type doubtful. Intense high over Finland, large stationary low area off Ireland. Mild southerly breezes over England, colder air to NE over North Sea.
596.	May 1st.	7·06 ,,	Weather overcast, raining. Cloud St. and Nb. 10/10. Inversion on up-trace from 0·36 km. to 0·53 km., Temp. 284 a. to 284·5 a., and isothermal layer up to 0·87 km., Temp. 284·5 a. Isothermal layer also near the surface on the down trace from about 0·2 km. to 0·93 km., Temp. 282 a. Large lapse rate in region of 10 km. Pressure distribution. Type VIII. Extensive high over Norwegian Sea, shallow low centred over Bay of Biscay region and spreading over western Europe. Moderate easterly or north-easterly winds over England.
597.	May 4th.	18·05 ,,	Weather cloudy. Cloud St-Cu. 3/10 (at 1200m. from NW'W), A-St. 6/10. Wind at 1800 m. nearly due west. Inversion on both traces 2·27 km. to 2·66 km., Temp. 266 a. to 268 a. Pressure distribution. Type X, modified. Low over Europe with centres over southern Norway, Switzerland and Hungary. "Sinuosities" over British Isles. Narrow Icelandic high, low over Azores. Northerly winds over British Isles everywhere.
598.	May 7th.	8·08 ,,	Weather overcast, raining. Nb. at 400 m. from NW'W. No inversion or other features noted, but the trace was a poor one. Pressure distribution. Type I, modified. High west of Ireland and also over France, large low area over North Sea with several centres (Denmark, west Norway and east England).
599.	May 7th.	13·05 ,,	Weather overcast after rain. Cloud Nb. 8/10 at 400 m. from NW and St-Cu 2/10 at 1200 m. from NW'W. No inversions or other features were noted. Tropopause below 8 km., but type unknown. Many gaps in record, so that a great deal of interpolation had to be resorted to. Pressure distribution. Type doubtful. High west of Ireland and over Iceland, lows over North Sea region and Europe with a shallow centre over the English Midlands. Moderate breezes circulating over England. Becoming Type X later.
600.	May 7th.	17·55 ,,	Weather cloudy after rain. Cloud Nb. 7/10 at 1200 m. from NNE, St.Cu 3/10. Pilot balloon ascent gave wind NE 9 m/s at 600 m. and NNE 9 m/s at 1200 m. No inversions or other features were noted. Below 0·9 km. the ascending record only was used. Pressure distribution. Type X, modified. High centred S of Iceland with a long tongue to Bay of Biscay, shallow low centred over East Anglia. Conditions still cyclonic over England.
601.	May 8th.	1·03 ,,	Weather fair. Cloud Ci. 5/10. Small but definite inversion shown on both traces 1·96 km. to 2·06 km., Temp. 265·5 a. to 265·8 a. Trace of isothermal layer coming down at 2·66 km., Temp. 262·5 a. Pressure distribution. Type X, modified. High west of Iceland, low over Holland. N and NW winds over Britain.

NOTES ON PREVAILING WEATHER CONDITIONS AT TIME OF ASCENTS, 1926.

No. of Ascent.	Date.	Time.	
602.	May 8th.	7.10 G.M.T.	Weather fair. Cloud A-Cu. 4/10 from N'W. Pilot balloon ascent showed wind NW 2 m/s at 300m. becoming N 13 m/s at 2400 m. Isothermal layer on both traces, mean 0·97 km. to 1·10 km. Temp. 270·5 a. Second isothermal layer on up trace 2·95 km. to 3·23 km., Temp. 258 a., on down trace 2·56 km. to 2·75 km., Temp. 259·5 a. Inversion on down trace 2·75 km. to 2.89 km., Temp. 259·5 a. to 260·5 a. Isothermal layers on both traces, mean from 3·49 km. to 3·83 km., Temp. 257 a. Pressure distribution. Type X. High west of Ireland, low region over eastern North Sea. Mainly northerly winds over Britain with passing rain, hail or sleet showers.
603.	May 8th.	12.50 „	Weather overcast with slight rain. Cloud Nb. 10/10 from NNE at 500 m. Inversion on down trace from 3·12 km. to 3·38 km., Temp. 256·5 a. to 257·5 a. Isothermal layer on down trace from 3·65 km. to 3·91 km., Temp. 256·5 a. Small isothermal layer on up trace from 5·43 km. to 5·60 km., Temp. 250 a. (Up trace shows nearly isothermal layer also from 2·95 km. to 3·56 km., Temp 259·5 a. to 259 a.) Pressure distribution. Type X. High west of Ireland, low towards Baltic and eastern North Sea. Low developing over Iceland.
604.	May 9th.	7.00 „	Weather fine and cloudless. Slight inversion 2·29 km. to 2·54 km., Temps. 261·5 a. to 261·8 a. Pressure distribution. Type I. Atlantic high has receded westward from Ireland, with tongue of high pressure stretching eastward to France. Icelandic low deepening rapidly in same position, low also centred over eastern Baltic.
605.	May 10th.	17.55 „	Weather cloudy. St. 1/10 at 800 m. St-Cu. 6/10. A-Cu. 1/10. Inversion on down (?) trace 1·69 km. to 1·77 km., Temps. 268 a. to 269 a. Isothermals ditto 3.46 km. to 3·74 km., Temp. 257 a. and 6·33 km. to 6·58 km., Temp. 240 a. Below 1·8 km. the warmer (ascending ?) record was used entirely. Pressure distribution. Type Va modified. Low over most of Europe. Large depression between Iceland and Ireland and low over Baltic and Mediterranean. Small secondaries over England, but mainly fair with SW wind. Barometer ceased falling over Ireland.
606.	May 10th.	18.02 „	Weather overcast, slight drizzle. St-Cu. 10/10. Isothermal layers on down trace only 3·15 km. to 3·33 km., Temp. 262·5 a. and 4·28 km. to 4·45 km., Temp. 256 a. Pressure distribution. See foregoing.
607.	May 11th.	17.50 „	Weather fine. Cu. and St-Cu 3/10, A-Cu. 1/10. Wind at 1800 m., WSW 10 m/s. Inversion on both traces 6·19 km. to 6·49 km., Temps. 240·5 a. to 241 a. A large lapse rate exceeding the dry adrabatic was found near the ground accompanied by a wind of about 10 m/s. This seems improbable. The surface temperature was obtained by a whirled thermometer and may be taken as accurate. Pressure distribution. Type III, modified. Large low persisting NW of Ireland, developing later into a "dumbell."
609.	May 14th.	7.45 „	Weather cloudy. St-Cu. 8/10 from N at 1400 m. Fr-Cu. 1/10 at 750 m. Wind at 300 m., ENE 4 m/s.; at 1200 m., N 6 m/s. Isothermal layer on both traces 2·73 km. to 3·01 km., Temp. 261 a. and on down trace only 6·09 km. to 6·29 km., Temp. 235 a. Below 1 km. the ascending record only was used. Pressure distribution. Type X. High west of Ireland, Main low over Norway and North Sea. Cool northerly current over Britain, shallow low forming later in the day over England.
611.	May 17th.	18.08 „	Weather fine. Ci-St. 2/10. Wind at 600 m., NW 12 m/s.; at 1800 m., N 4 m/s. Isothermal layer on both traces 2·04 km. to 2·33 km., Temp. 267·5 a. Pressure distribution. Type IV. High persisting over Azores with a broad wedge over Britain; lows over the Baltic and Germany and SW of Iceland.
612.	May 19th.	7.25 „	Weather fine and hazy. Cu. 1/10. Wind at 300 m., SE 6 m/s.; at 1200 m., ESE 5 m/s. Small inversion on both traces 2·81 km. to 3·08 km., Temps. 261 a. to 261·5 a. Small isothermal on both 4·24 km. to 4·38 km., Temp. 258 a. Pressure distribution. Type doubtful. Large shallow low area off SW Ireland, small secondary in Channel. High in Norwegian sea and pressure becoming generally uniform over Europe. The low off Ireland had filled up rapidly during the night.
613.	May 22nd.	7.29 „	Weather fair or cloudy, hazy. A-Cu. 8/10 moving very slowly from W. Isothermal layer on both traces 3·37 km. to 3·74 km., Temp. 263·5 a. Pressure distribution. Type doubtful. Long narrow wedge from Madeira to the Faroes; pressure very uniform to the eastward. Large low stationary over Eastern Atlantic. Shallow low over southern North Sea.

542. **1926.**

NOTES ON PREVAILING WEATHER CONDITIONS AT TIME OF ASCENTS, 1926.

No. of Ascent.	Date.	Time.	
614.	May 25th.	18.04 G.M.T.	Weather fair. Cu. and St-Cu. 5/10. Region of small lapse rate from 2·00 km. to 2·37 km., Temps. 277 a. to 276 a. Pressure distribution. Type doubtful. Anticyclone over western Europe; long ridge with a centre over Denmark joining the Azores and Arctic highs. Low over the eastern Atlantic. Light northerly breezes over England.
615.	May 28th.	13.06 „	Weather cloudy, passing showers. St-Cu. 3/10 from SW, Cu. 3/10, and Cu-Nb. 3/10. Inversion on up trace 2·28 km. to 2·43 km, Temps. 274 a. to 275 a. Pressure distribution. Type Va, modified. Low area to the NW of the British Isles, high N of Iceland and over Azores, low area developing several centres. Variable to fair weather over England with light to fresh SW winds.
616.	May 31st.	17.48 „	Weather cloudy. St-Cu. 7/10, A-Cu. 1/10. Pressure distribution. Type II. Large low area from W of the Faroes over Norway, breaking later into several centres. High over Azores and N Russia.
617.	July 12th.	11.30 „	Weather cloudy and very hot. St-Cu. and small Cu. 8/10, cloud increasing. Inversion (especially marked on up trace) on both traces, mean 1·95 km. to 2·18 km., Temps. 283 a. to 284·5 a. Pressure distribution. Type VI or VIa. Anticyclone centred over W. Germany covering most of Britain. Deep low S of Iceland. Southerly wind over Britain.
618.	Aug. 10th.	14.34 „	Weather overcast. St. and Mam. Cu. 10/10. Inversion on down trace 2·75 km. to 3·01 km., Temps. 271·5 a. to 273 a. Pressure distribution. Type III. Extensive shallow low area centred NW of Scotland with a secondary trough (moving eastward) over SE England and France. High over Azores. Moderate W and SW winds over England.
620.	Sept. 14th.	7.45 „	Weather cloudy. Cu. 4/10 from WNW at 750 m., Ci. 3/10 from W. Marked inversion on up trace at 1·60 km. to 2·12 km., Temps. 275 a. to 277 a. Rel. humidity from 92% to 63%. On down trace 1·37 km. to 1·56 km., Temps. 276·5 a. to 279·5 a. Rel. humidity 75% (?) to 52%. Isothermal layer 2·49 km. to 2·90 km., Temp. 274 a. Rel. humidity from 85% to 52%. Pressure distribution. Type IV, slightly modified by a small low over the Hebrides. Anticyclone centred over the west of France with a broad wedge over the British Isles and northward. Small low over the Hebrides filling up, main low areas south of Iceland and over the Arctic.
621.	Sept. 14th.	17.45 „	Weather overcast, raining slightly. St. 9/10 at 250 m. from SW, St-Cu. 1/10. Very slight inversion on both traces 4·30 km. to 4·40 km., Temp. about 264·5 a. Pressure distribution. Type doubtful. High centred over France, low south of Iceland moving eastward later and becoming deeper.
622.	Sept. 15th.	7.55 „	Weather cloudy. St. 5/10 from WSW at 300 m., St-Cu. 4/10 from W'S at 1100 m. Isothermal layer on both traces 2·23 km. to 2·50 km., Temp. 276. Ditto 5·20 km. to 5·45 km., Temp. 258 a. Ditto 5·75 km. to 6·15 km., Temp. 255 a. A large lapse rate exceeding the dry adiabatic was found near the ground accompanied by a wind of about 10 m/s. This seems improbable. The surface temperature was obtained by means of a whirled thermometer and may be taken as accurate. Pressure distribution. Type II, becoming IV. Low near the Shetlands moving eastwards, with transient wedge extension of the Azores-Central Europe high following.
624.	Sept. 16th.	7.48 „	Weather fair. Ci. 4/10. NW'W. Wind at 600 m. SW'S, 2 m/s. At 1200 m. NW'W, 8/ms. Marked inversion on both traces 1·00 km. to 1·20 km., Temps. 281 a. to 282·5 a. Relative humidity from about 65% to 40%. Small isothermal layer at 4·15 km., Temp. 269·5 a. Pressure distribution. Type IV, becoming V. High centred over France with wedge extension northward over Britain. Deep low SW of Iceland moving NE. The anticyclone was dominant all day over southern England.
628.	Nov. 6th.	12.09 „	Weather overcast with continuous rain and falling barometer. Cloud sheet at about 700 m. Rather poor record. For the most part only one record was visible and some gaps occurred in that, in which the temperature was estimated. Pressure distribution. Type Va. Deep depression filling up to the SE of Iceland and a small secondary about to cross northern England.

T = Temperature in Degrees Absolute. P = Pressure in millibars.
H = Height in kilometres above M.S.L. RH = Relative Humidity per cent.
