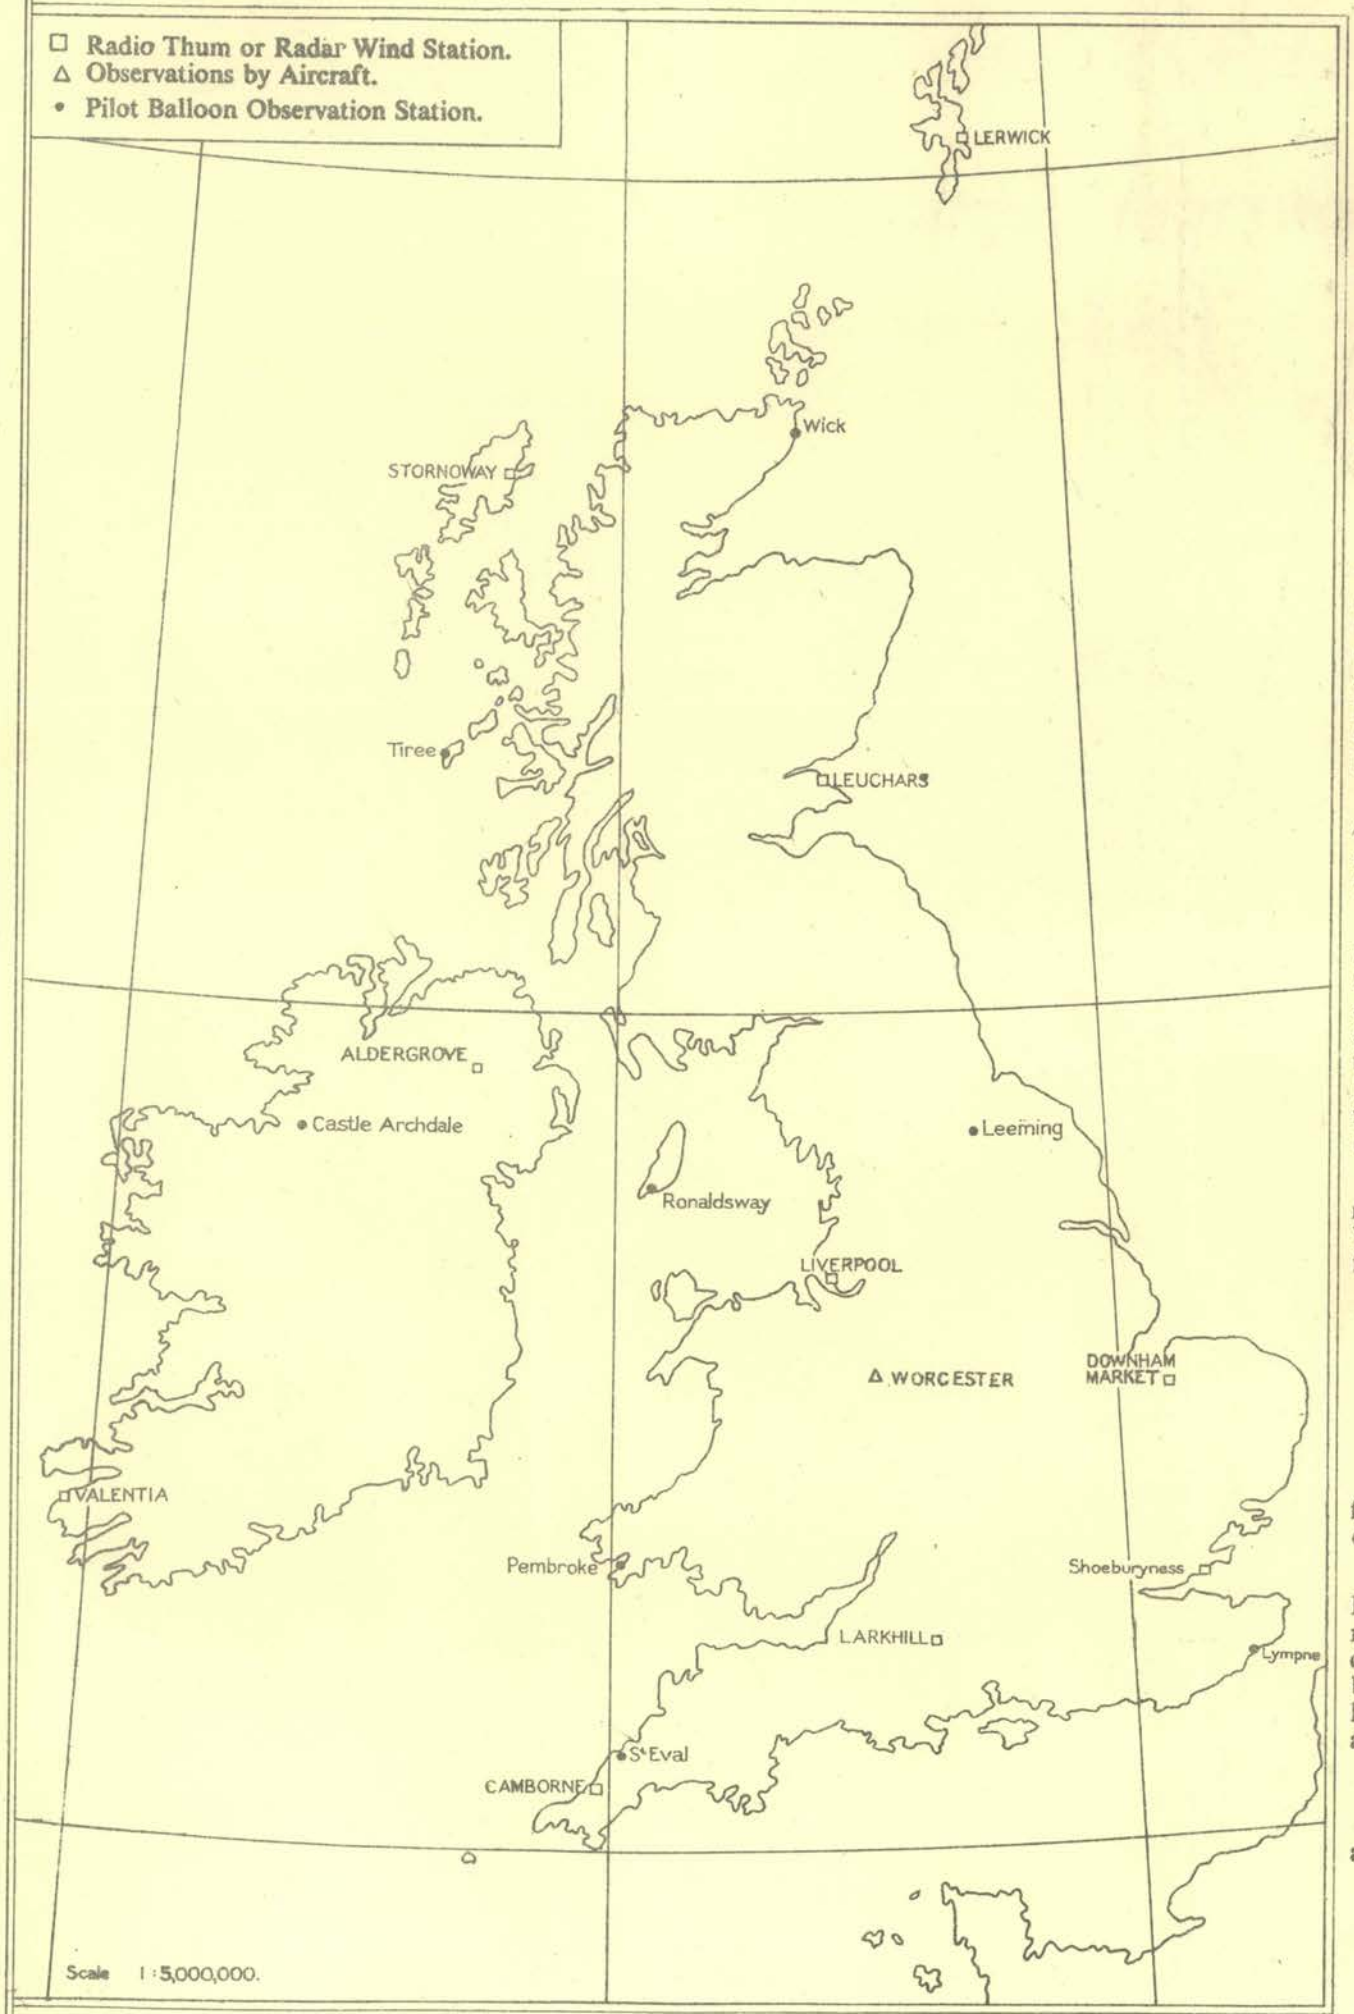
INTRODUCTION



THE DAILY AEROLOGICAL RECORD.

Prior to 1st January, 1950, upper air data and charts derived therefrom were published in the Upper Air Section of the Daily Weather Report. With effect from that date the Upper Air and International Sections have been discontinued, the former being replaced by the Daily Aerological Record of which this is the first volume.

Upper Air Temperature and Humidity.—Observations in the British Isles are made by radio-sonde at Camborne, Larkhill, Liverpool, Downham Market, Aldergrove, Valentia, Leuchars, Stornoway and Lerwick, and from ocean weather ships at 53°50′ N., 18°40′ W. and 60°00′ N., 20°00′ W. Observations are also made by meteorological reconnaissance aircraft over the Atlantic Ocean and by meteorological aircraft over Worcester

Observations by aircraft are normally made at 500, 1,000 and 1,500 feet above airfield level or as near the sea surface as possible and then at pressures of (1,000), 950, 900, 850 etc. millibars, and at temperature inversions. The values of dew point are computed from readings of dry and wet bulb thermometers using tables based on the relationships :—

$e' = e_w(t') - 0{\cdot}37\,(t-t')\,P/1000$ for t' above 32°F.

$e' = e_i(t') - 0{\cdot}33\,(t-t')\,P/1000$ for $t' = 32°$ F or below

where e' is the vapour pressure of the air of which the pressure is P, t and t' are the dry and wet bulb temperatures (°F.), $e_w(t')$ is the saturation pressure with respect to water at temperature t' and $e_i(t')$ is the saturation pressure with respect to ice at temperature t'. For temperatures 32° F and below, the wet bulb is assumed to be covered with ice and the dew point is the temperature for which e' is the saturation pressure with respect to supercooled water. On account of the difficulty of ensuring correct functioning of an ice covered wet bulb, the values of dew point cannot be regarded as always reliable when t is below 32° F.

Radio-sonde observations are reported for the standard levels of 1,000, 950, 900 etc. millibars, and at intermediate levels as necessary to represent the results of the ascent. The values of dew point are derived from readings of relative humidity furnished by a gold-beaters skin hygrometer which forms part of the radio-sonde.

Heights.—The heights are computed from the values of temperature, pressure and humidity : the gravitational acceleration g is assumed constant and equal to 980·62 cm sec^{-2}, being that at latitude 45° at sea level : the gas-constant R is taken as $2{\cdot}8703 \times 10^6$ erg gm^{-1} deg. C^{-1} : the air density at 1,000 mb. and 0° C. is taken as ·0012762 gm cm^{-3}. The height corresponding to the pressure of 1,000 mb. is interpolated or extrapolated, according as the M.S.L. pressure is above or below 1,000mb. In drawing the contours of the 700, 500 and 300 mb. surfaces as reproduced in the charts, assistance is obtained from the observations of wind at or near those levels.

Height and type of Tropopause.—For the purpose of identifying the Tropopause, rules similar to those employed in the Aerological Section of the Observatories Year Book are employed. Three types of tropopause are recognised, defined as follows :

Type I. The tropopause is indicated by a definite inversion.

Type II. There is no inversion, but a sharp discontinuity, the lapse rate above the discontinuity being 1° F. per 1,000 feet or less.

Type III. There is neither an inversion nor a discontinuity, but the lapse rate falls gradually to a value less than 1° F. per 1,000 feet. The point where the lapse rate drops to the value is taken as the tropopause.

In view of the arbitrary character of the definition of Type III, it is frequently found necessary to disregard a Type III tropopause in charting the contours reproduced on p. 1 of the Report.

Upper Winds.—The upper winds reported by Aldergrove, Downham Market, Larkhill, Liverpool, Lerwick, Shoeburyness, Stornoway, Valentia, Leuchars, are measured by Radar methods, the mean winds being measured over 3,000 feet layers centred at standard pressure levels. Most other reports refer to ordinary pilot balloons observed by theodolite. The results are expressed in knots referring to layers 500 ft. thick centred approximately at the levels 1,000, 2,000, 3,000 etc. feet above Mean Sea Level.

The direction is specified in degrees from true north measured through east.

Abbreviations. Besides the standard abbreviations for cloud forms the following are also used :—

HNG (height not given), TNG (top not given), TNR (top not reached), NR (not reached).

NOTES ON THE AEROLOGICAL SITUATION.

The warm ridge on the central Atlantic moved some 700 miles east and a strong northwesterly thermal gradient formed on its forward side leading to the cold trough which crossed Britain during the day. Late in the period the cold trough began to degenerate and the strong northwesterly thermal slackened to about half its earlier value.

The continuous lines are contour lines of the 300 mb. surface
The dotted lines are isopleths of the thickness of the layer 500 – 300 mb.

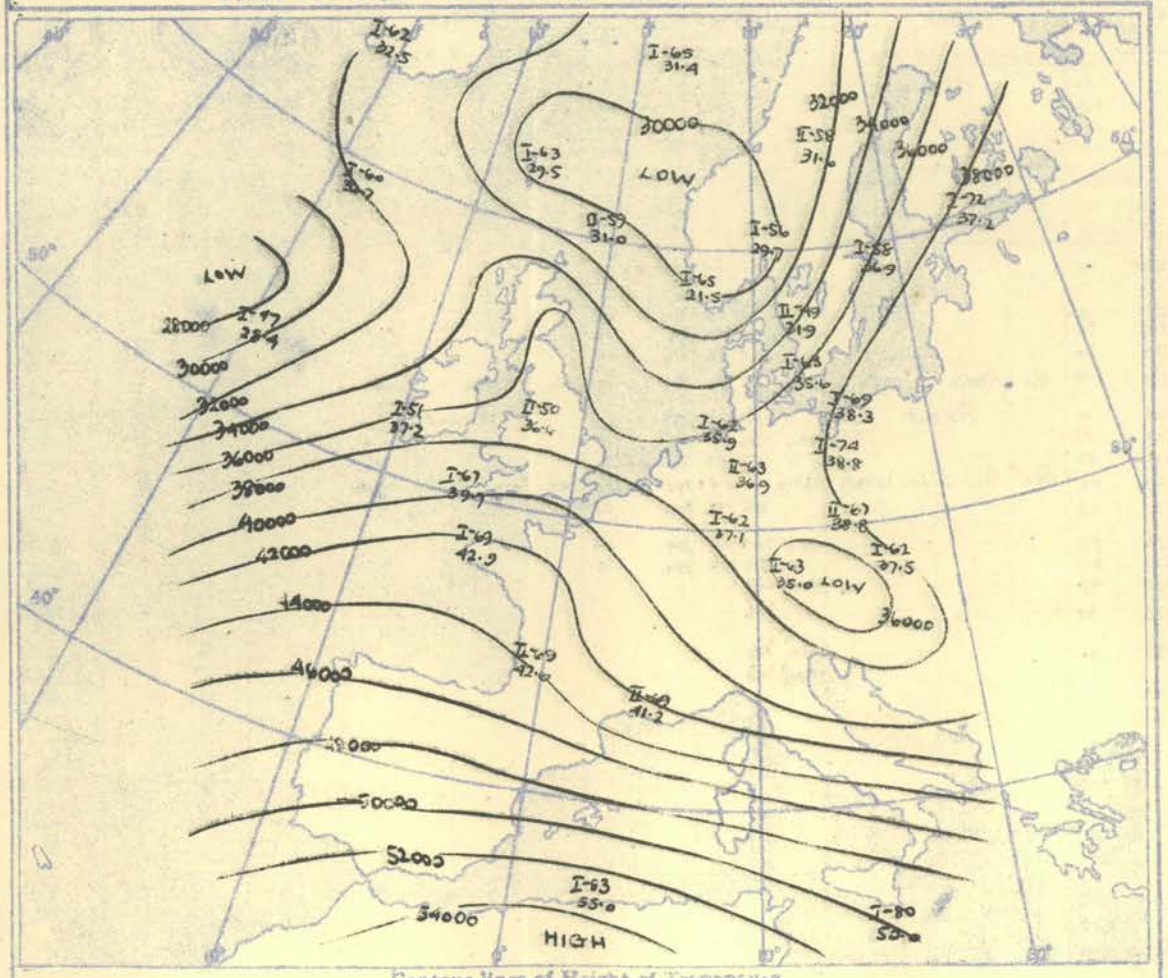
TROPOPAUSE CHART at about 15h. G.M.T.



Contour lines of Height of Tropopause.
Temperature of Tropopause.

NOTES ON THE AEROLOGICAL SITUATION.

The main feature of the charts is the sharpening of the trough which extended over the North Sea and Eastern districts of Great Britain. This trough apparently absorbs the smaller troughs moving eastward across the Atlantic.

NOTES ON THE AEROLOGICAL SITUATION.

The wave pattern in the thermal distribution increased somewhat in amplitude due to a Southward thrust of cold air over Eastern Europe, to an intensification of the cold pool near the Azores, and to the approach of a further cold trough in the Northwest Atlantic.

NOTES ON THE AEROLOGICAL SITUATION.

Cold pool which had moved from the Azores was still showing in the Western English Channel at 1500 Z. Movement eastward of this cold pool and the cold trough which extended southwards from Iceland brought unstable thundery conditions to the British Isles.
