## 1 INTRODUCTION

TRENDS<sup>1</sup> are 2-hour forecasts appended to Meteorological Actuarial Reports (METARS<sup>1</sup>). METARS are produced at all airports every half an hour. Not all airports add on a TREND to the METARS as this requires the knowledge and resources of a forecasting centre. This means that TRENDS are generally written by people who are not on site at the airport concerned.

TRENDS are an additional, short-term source of information for airports and pilots etc. on top of the 9 or 18-hour terminal aerodrome forecasts (TAFs). This information is used to make decisions about diverting aircraft or holding them at departure during bad weather etc. Such diversions and delays are costly to the airline in terms of increased fuel load, transportation of passengers arriving at the wrong airport, having aircraft in the wrong place at the wrong time, and conversely if diversions and delays are not made the plane and passengers may be put into danger.

The work in this report was undertaken to assess the reliability of TRENDS. There is currently a decline in the number of airports producing TRENDS and it therefore seems especially suitable to carry out a verification of them at this time, to see if this decline is deserved. Six months worth of data has been used from each of four airports - Heathrow, Manchester, Glasgow and Belfast - to verify the TRENDS produced for them. Verification is achieved by comparison of the forecast with the actual data as supplied in the METARS.

Two major factors for concern have been tested, namely visibility and cloud base height. The programs used to test the data were written in FORTRAN 77, outputting the results as contingency tables. The data was obtained from the observational database of the UK Meteorological Office (MetDB).

## 2 METHOD.

There are three kinds of change reported in a TREND: NOSIG, TEMPO and BECMG:

- ◆ NOSIG states that the forecast element will stay within certain specified boundaries<sup>1</sup> (i.e. the persistence forecast).
- ◆ TEMPO indicates a change that will happen for only part of the duration of the TREND.
- ◆ BECMG indicates a gradual change in the conditions.

Certain assumptions were used to model these kinds of changes based on the work done by Neil Gordon on verification of TAFs (Gordon, 1989). TEMPO has been assumed to mean that the change will occur throughout the specified time<sup>2</sup> (this is somewhat pessimistic, but for aviation purposes the worst case must be assumed). BECMG is taken to mean a linear change over the specified time (as in Neil Gordon's scheme).

The Cloud Base Height has been taken as the height of the lowest reported/forecast layer of cloud to cover more than 2 oktas of sky. This is reasonable since below 3 OKTAS cloud cover is insignificant to airports and pilots. (Note that both METARS and TRENDS allow for 3 layers of cloud to be reported, and these are given in ascending height order).

Further assumptions were made to deal with the presence of the three TREND and METAR reporting categories: Ceiling And Visibility OK (CAVOK), Sky Clear (SKC) and Nil Significant Cloud (NSC). When these codes were found the values of visibility and cloud base height were replaced with a constant high value. For visibility this was taken as 10000m since no visibility about 9999m is ever reported. For cloud base height the value of 5015ft was used for similar reasons.

Note also that the 3 separate TREND groups allowed for in the coding for each TREND have been allowed for in the testing, however it was found that only the first group was used in all the data tested. This seems reasonable as the TREND only covers 2 hours and only rarely would one expect such rapid and varied change to require 3 TREND groups.

If more than one TREND group were to be reported, all the TRENDS given would be tested regardless of whether they overlapped each other. This would lead to some conflict with the possibility of the forecaster being both correct and

---

<sup>1</sup> For detailed information on TRENDS and METARS and their coding see: WMO - No 782 (Revised 1 January 1996) Aerodrome reports and Forecasts. A users' guide to the codes.

<sup>2</sup> TREND forecasts allow for a from/until/at time to be specified as limits to the change in conditions. Although these were not found to be used in the data tested, they have been allowed for in the testing programs, defaulting to the whole two-hour forecast period.

incorrect at the same time. If a second or third group were ever to be reported then an inspection of the whole TREND, to identify any such conflicts, would be necessary.

Since a TREND covers a period of two hours, one TREND is tested against the following four METARs. A full explanation of all the programs used is given in the documentation kept with them in the Aviation Group, Forecasting Products Branch, at the Met. Office.

### 3 RESULTS AND DISCUSSION.

The full set of contingency tables<sup>3</sup> produced are set out in Appendix I. Below are the results on the full six months data from Heathrow, both for visibility and cloud base height (CBH).

As a cursory glance will show, the diagonals (top left to bottom right) are well populated indicating generally good forecasting.

Note that the extreme bias to the bottom right corner is due both to the varying width of the test bands used (these values are used because these are deemed to be the significant changes in the WMO booklet on METARs) and also the infrequency of lower visibility conditions.

Fig.2: CBH contingency table for Heathrow: October 1997 - March 1998

<sup>3</sup> Contingency tables: These are a way of displaying frequency data in an easy to understand way. When a forecast value is given this determines the column in which the point will be placed, and similarly the actual value taken at the forecast time determines the row. Thus a correct forecast will add a point on the diagonal from top left to bottom right.

**Fig.3: Qualitative description of contingency table areas**

On further inspection, some rare but important forecasting errors can be spotted. Note that the lower left corner indicates pessimistic forecasting, i.e. predicting lower visibility or CBH than actually occurred, and the top right corner indicates optimistic forecasting. High numbers in the pessimistic corner indicate expensive forecasting errors and high numbers in the optimistic corner indicate dangerous forecasting errors. The forecast should be biased to always err on the side of safety, and we would want to see this reflected in the results.

For example note the excessively pessimistic forecasting indicated by the ringed numbers. These are both due to one particularly difficult forecasting day in December 1997, when the prediction of the arrival and dispersion of fog was involved. This is always difficult to predict correctly and on this occasion the dispersion was completely misjudged. There was freezing fog present, which changed to patchy fog, but with the temperature and dew point still below zero, the forecaster predicted that the freezing fog would return. In fact what actually happened was that the fog turned to mist with a visibility of around 3000m, as opposed to that predicted of 500m.

Similar tables are shown for the other three airports tested: Manchester, Glasgow and Belfast.

Fig.7: CBH contingency table for Glasgow: October 1997 - March 1998

Note that the tables from Glasgow show a tendency to err towards the optimistic and more dangerous side - particularly with visibility. It can be seen from the monthly breakdown of the results (see Appendix I) that the majority of this optimistic forecasting occurred during October to December 1997.

Fig.9: CBH contingency table for Belfast: October 1997 - March 1998

#### 4 CONCLUSIONS.

1. TRENDS are a good forecast on the whole, however there are certain difficult conditions under which they perform badly over a short timescale, such as predicting the onset and lifting of fog.
2. Generally the view is for the forecasters to err on the pessimistic and therefore safer side, though more expensive to the airlines. This is as to be expected, however the pessimism is not so very large as to cause concern.. Glasgow is the exception to this, erring on the optimistic side.

#### 5 FURTHER STUDY.

1. Some investigation into the effect on the results of the model used here for TEMPO would be beneficial. It is expected that the effect of a different model would not be large given the short time period of the forecast, because the forecast can only be checked against 4 observations. Any attempt to use a probabilistic model for TEMPO would need some kind of interpolation between the observations to be carried out before verification. As a good starting point it is suggested that observing the effect of using a persistence model for TEMPO (as used for NOSIG) would show the possible extent of the model's effect on the results.
2. It would be worthwhile to see if the first hour of the TREND forecast performs any better than the second hour.
