

RAIN GAUGES

of approved design.

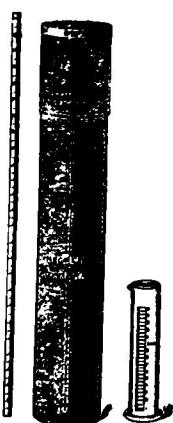

The "Snowdon":

the very well known pattern, with 5-in. diameter brass rim, complete with inner can, graduated glass bottle and measure.

"Meteorological Office" pattern, with 8-inch diameter brass rim, inside bucket and graduated glass measure. This is the type adopted by the Meteorological Office.

The "Mountain"

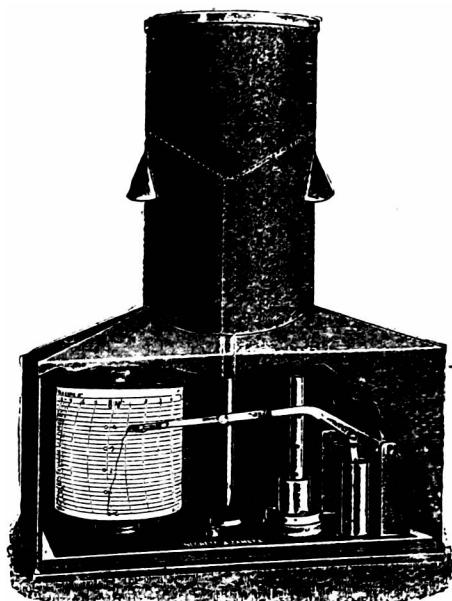

Gauge is designed for use where the instrument can be visited only at rare intervals. It holds 27 inches of rain, and is supplied with graduated rod, inner can, and glass measure holding 1½ ins.

Graduated Measures.

Our Measures are accurately calibrated and engine divided, the figures etched on by hand, and filled in with a white substance. They are superior in appearance, and in legibility.

In Recording Rain Gauges, the "Hyetograph" is a perfectly accurate and reliable instrument, distinguished by simplicity & originality.

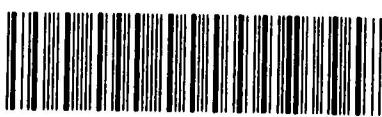

Illustrated price-lists of Rain Gauges, etc., will be gladly sent post free on application.

PREFACE.

THE late date at which this volume appears is due entirely to the effects of the third year of War. The editorial work has been finished at practically the same date as last year ; the delay has arisen mainly in the mechanical processes of block-making, printing and binding, but the old firms who have attended to these matters from the first issue of *British Rainfall* have done their utmost to overcome the difficulties as they arose. There has again been a perceptible reduction in the number of rainfall returns sent in as compared with the previous year ; but this reduction does not exceed 4 per cent. of the whole number, and returns from practically 5,200 stations are included.

In the compilation of the volume, Mr. Carle Salter, the Assistant Director, has, as in recent years, undertaken the responsibility for the statistics in Parts I. and II. and for the whole of Part III. He has also drawn most of the maps, the number of which has had to be reduced on account of the absence of both the experienced map draftsmen. He and the assistants have worked to the full limits of their strength, and such short-comings as may appear in the volume are the results of uncontrollable circumstances.

I have been able to take a larger personal share in the preparation of this volume than my health has permitted for several years, and I have written or thoroughly revised all the letterpress except where otherwise specified.

The volume will be found to give a very full account of the rainfall of the year. Special attention may be called to the Report of the Director on pp. 9-15, which refers to the work of the Rainfall Organization for the year, to the description in Part II. of the two remarkable Scottish rains of July 7th and October 11th on pp. [47] and [60] (the latter includes the largest fall in one day ever recorded in the British Isles, 8.20 inches, at Kinlochquoich), to the widespread rainfall in the south of England on August 29th, on p. [55], and to the fierce little Welsh downpour of July 26th on p. [53].

The monthly maps of rainfall on pp. [72-95], and the discussion of the total rainfall of the year, on pp. [114-122], also show some points of special interest.

H.R.M.

62, CAMDEN SQUARE,
LONDON, N.W. 1.
16th August, 1917.

OPTIMISM.

In the Hoosier dialect.

It ain't no use to grumble and complain ;
It's jest as cheap and easy to rejoice ;
Whén God sorts out the weather and sends rain,
W'y, Rain's my choice.

James Whitcomb Riley.

A Translation.

Futile it were to heave the fretful sigh
When facile mirth is free to such as I :
Should cheerless rain from high Olympus fall,
I choose wet weather, and record it all.

SEVENTH ANNUAL REPORT OF THE DIRECTOR TO THE TRUSTEES OF THE BRITISH RAINFALL ORGANIZATION.

Presented at the Meeting of Trustees held at 62, Camden Square London,
on August 7th, 1917.

The Late Sir Alexander Binnie.—By the death of Sir Alexander Binnie on May 18th, 1917, the Trustees have lost one of their colleagues who before the breakdown of his health took a great personal interest in the work of the Organization. He represented the engineering profession which more than any other part of the community turns to practical account the data collected by Observers, and he also contributed in a great degree to the establishment of definite principles relating to the fluctuations of annual rainfall and the period required to yield normal values. An obituary notice was published in *Symons's Meteorological Magazine* for June, 1917, and a short biography, illustrated by a portrait, appears in *British Rainfall, 1916*.

The Routine Work and the War.—It is with surprise and deep satisfaction that I am able to report the smallness in the reduction of the volume of rainfall observations received for 1916. Many old records have been stopped owing to the war, but not a few new Observers have come to our aid, thus keeping the total number to nearly 5200. Much of the observing work is being done by willing substitutes for men who have gone to the front, and thus any fear that the voluntary system of rainfall observing might break down in the stress of circumstances has proved vain.

The work of the office has, however, been beset with great difficulties, partly on account of reduced income, but to a much larger extent by the loss of all assistants of military age. Mr. H. E. Carter, the Chief Computer, continues to work in the Meteorological Section of the Royal Engineers at General Head Quarters in France. Mr. D. S. Salter, Cartographer, after serving a year in the Royal Engineers, received a commission in the Royal Garrison Artillery, and is now at the front. Mr. J. Glasspoole took the degree of B.Sc. in Chemistry and Mathematics at the University of

London in October, 1916, and received an appointment as assistant chemist in a Government laboratory. L. G. McCutcheon, assistant draftsman, gave up his position before being called on to join the Army ; C. Evans, who had just left school, was engaged in December to act as junior assistant in all departments and he has proved a quick learner. Mr. F. Wuyts, who will shortly be called up for the Belgian Army, has become a most useful assistant, and Mr. R. Lamport continues the faithful and accurate service which he has rendered for more than thirty years. Mr. Mossman, except for unavoidable absences through illness, has been specially engaged in editorial work, but has always most willingly turned his hand to any other branch where the pressure of circumstances required it. The brunt of all the difficulties arising from changes in the staff fell upon Mr. Salter, who has throughout proved equal to the emergencies. In the absence of the trained draftsmen he has plotted most of the current monthly and other rainfall maps and generally has undertaken any piece of work which no one else could be found to do. This of course has all been in addition to his ordinary duties as Assistant Director, the main part of which consists in correspondence with Observers, settling discrepancies in the returns, and compiling the General Table for *British Rainfall*. During their short periods of leave, Mr. D. S. Salter and Mr. Glasspoole have voluntarily given useful assistance in the office work. I must put on record here the great help which has been given by Mr. J. Fairgrieve in filling up the monthly rainfall maps for 1916 with the returns received at the beginning of the year, and also in plotting several of the maps of daily rainfall for the volume now being completed. Much valuable help has also been given by Mr. M. J. Salter in computing and checking the tables for *British Rainfall* and in other ways.

Our ambition has been confined to keeping the records and publications going with undiminished accuracy, all plans of improvement or extension of the scope of the work have had to be postponed.

Original Observers.—Of the six Observers referred to last year whose contributions were first published in *British Rainfall, 1860-61*, I regret to have to announce the death, on December 16th, 1916, of Rev. C. B. Mount, who had ceased to observe for many years. The list now includes :—

R. BURRELL, Esq.

W. S. CLARKE, Esq.

J. G. WOOD, Esq.

DR. W. C. LAKE.

LORD PECKOVER OF WISBECH

Metric Units and Summer Time.—Two causes of confusion in observing and increased difficulty in the detection and correction of errors which have hampered our work since last year are not directly due to the war. The more serious of these is the introduction of rain measurements in millimetres by the Meteorological Office, the effect of which begins to be felt in the records for 1916. As it is impossible to make any changes this year in the handling of statistics I must again postpone the discussion of the matter. The difficulties I refer to have been due to the necessity of attempting to convert two incommensurable units. If the metric system is generally adopted in this country and becomes familiar to the majority of the people, we should certainly drop the inch; but at present it seems to be the duty of this Organization to abide by the units that are generally understood in the country.

Summer Time has brought doubt and confusion into the discussion of heavy falls on rainfall days, as although the Observer who goes by the clock has only one day of 23 hours and one of 25 hours in the year, his 24-hour day throughout the whole period of Summer Time begins an hour before the normal rainfall day based on Greenwich mean time. The real trouble is that it is almost impossible to ascertain whether any particular Observer has used Summer Time or not. In one case, at least, an Observer anxious to adhere to Greenwich time took his readings at 8 a.m. Summer Time! Several Observers have unfortunately used the expression "Sun time" to denote Greenwich time, while others have used "Sum. time" to denote Summer time, and where a typewriter is not used the boundary line between "n" and "m" is deplorably vague.

Inspection of Rain Gauges.—This branch of the work has suffered most on account of the absence of the senior assistants and the few opportunities which Mr. Salter or I have had to leave home. I have seen 39 gauges in the period since my last report, of which 5 were in London, 2 in Surrey, 3 in Hampshire, 1 in Dorset, 6 in Wiltshire, 3 in Somersetshire, 6 in Monmouthshire, and 13 in Breconshire. Mr. Salter has inspected 18 gauges, 3 in Middlesex, 1 in Hertfordshire, 5 in Sussex, 8 in Dorset, and 1 in Somerset, and Mr. Mossman 2, in Middlesex.

The Publications.—All the curtailments introduced last year have been retained, and brevity has been the motto in all discussions. In order to save paper and reduce expense in *British Rainfall* all illustra-

tions, except the monthly maps, have been cut out or kept to a minimum. At the same time no essential record or discussion has been omitted from *British Rainfall, 1916*, which as far as statistics are concerned, is as complete as ever. The new volume consists of 306 pp. as compared with 338 pp. in *British Rainfall, 1915*, 448 pp. in *British Rainfall, 1914*, and 476 pp. in *British Rainfall, 1913*.

Symons's Meteorological Magazine has been kept down to 12 pages monthly instead of 16, as last year, and 20 in 1914. It has appeared with perfect regularity, and the difficulty has been not to get material for publication, but to decide what must be left out. The tables appearing monthly have been modified so as to save space without reducing the number of stations from which reports are published.

Scientific Work and Advice.—I have continued the custom of supplying an early summary of the rainfall returns of the year to *The Times*, and I have also sent letters to that paper on any unprecedented records in the meteorological observations at Camden Square, which have been exceptionally numerous in the last twelve months.

As usual there has been a large number of questions from members of the public regarding the rainfall of various localities to help in the choice of a residence, suggesting new forms of meteorological instruments, enquiring as to the validity of weather signs and the like, all of which have been answered in detail. Another considerable portion of the correspondence consists of vague questions such as "Please inform as to water indicators," or "Kindly state on attached card the rainfall of London or of all England." These naturally require no expenditure of time in answering.

Comparatively few enquiries have been made which involved much trouble, but I may mention the preparation of a small scale average rainfall map of Ireland in response to a request from the National Health Insurance Commission in Dublin. We have advised the Committee for the Investigation of Atmospheric Pollution on points connected with the rainfall at some of their collecting stations, and supplied information to the London County Council and various municipal authorities. I have also been in correspondence with several investigators engaged in researches which involve the construction of rainfall maps of localities, and other matters in which rainfall and evaporation are concerned. We have again sent a

circular from Captain Cave to all the Observers inviting them to assist the Meteorological Office by contributing notes of winter thunderstorms, and I believe that the response has been satisfactory. We have endeavoured to induce several local authorities, in some instances with success, to continue valuable series of observations which we had been informed were in danger of being stopped.

In addition to these gratuitous services many interviews have been given to newspaper correspondents for a small fee, and data have been supplied for payment to a number of persons and public bodies who did not propose to use them for purely scientific work. Monthly maps of rainfall have been supplied regularly to the Meteorological Office for publication in the *Monthly Weather Report* on the same terms as before.

Mr. Salter read a paper to the Royal Meteorological Society on "The Measurement of Rainfall Duration," the substance of which appears in Part I. of *British Rainfall, 1916*. He has served on the Council of the Royal Meteorological Society and he and I have taken part in the discussions at several meetings.

Professional Work by the Director.—Under Clause 25 of the Trust Deed I have continued to act as Rainfall Expert to the Metropolitan Water Board, and as Referee under the Abertillery and District Joint Water Board Act, 1910, and I have as in previous years supplied tables of rainfall to the Thames Conservancy and reports on the rainfall of the Birmingham and the Birkenhead Water Works in Wales. I have also reported on the rainfall of proposed gathering grounds for the Barrow-in-Furness Water Bill, 1917, and for other areas in the north of England, Wales and Scotland.

Legacies to the Trustees.—The late Mr. George Searle of West Kensington, who died on August 23rd, 1916, left to the Trustees of the Organization his set of *British Rainfall* and *Symons's Meteorological Magazine*, together with a sum of £200 free of legacy duty. This will not be payable for some time.

The executors of the late Mr. W. B. Butler, of Southgate, who died on May 29th, 1917, have handed to us a nearly complete set of volumes of *British Rainfall* and of *Symons's Meteorological Magazine* and a collection of meteorological instruments, including some very interesting travellers' rain gauges of small diameter. They have also intimated a bequest of £100 free of legacy duty.

A legacy of £10 has been received from Mr. L. J. Nicholson, a comparatively recent Observer, whose help in checking rainfall returns was acknowledged in my last report. Mr. Nicholson was killed in action in France, in May, 1917.

The executors of the late Mr. George Pile, of Cranbrook, have forwarded the manuscript of weather notes and rainfall returns kept for more than 40 years, and left to the Organization.

Mr. Gerald Stephens, of Worcester Park, Surrey, has kindly presented a set of *British Rainfall* containing several volumes that have long been out of print.

Adventure of a Rain Record.—Mr. J. G. K. Day, of Cowes, Isle of Wight, in sending his record for 1916, says :—

“ It is with pleasure I am able to send to you this year as when I saw the flames leaping through the office I thought everything in it would be destroyed as, unfortunately, we have had a serious fire in the works this year. I lost records, of rainfall from 1882 as well as other meteorological data, and but for the hose playing on to the sheet I had hung up of last year's rainfall it would have been destroyed. As it was the melted lead ran down across it, but I can still read it.”

We were happily able to supply Mr. Day with a copy of all the rainfall records, the originals of which were lost in the fire.

The General Fund.—As usual I submit a summary of the receipts and expenses of the Organization for the finance of which I am personally responsible under the Trust Deed. Detailed books are kept and these are open to the inspection of any subscriber to the fund on personal application at 62, Camden Square. I doubt whether any work of equal magnitude is carried out at a smaller cost. It could be done very much better if it were adequately supported, and but for the war, I should have continued the effort begun in 1913 to obtain a satisfactory basis for continuing and improving the work of the Organization. I am thoroughly persuaded that work of this kind is most efficiently carried on by a voluntary agency absolutely free from red tape; but to secure this efficiency the generous help of the well-to-do Observers is as necessary as the devoted services of the staff. It is clear that to continue the work in the old way means far too heavy a strain on the strength of the Director and his helpers; but at a time like the present it is hopeless to seek to improve the conditions. It is a marvellous thing that the work has survived three years of war distractions and restrictions, and we

are confident that in the future some way will be found, though it has not yet appeared, for giving its proper place in the Sun to the national study of the great national resource of Rain.

HUGH ROBERT MILL.

TREASURER'S REPORT ON ENDOWMENT FUND.

STATEMENT FOR THE YEAR, 1916.

The following sums have been received :—

	£	s.	d.
Balance from 1915	41 9 11
R. Cooke, Esq. (7th Don.)	4 5 0
Under £2	2 0 0
			<hr/>
			£47 14 11
			<hr/>

No expenditure has been made during the year.

On August 7th, 1917, the Trustees held as the Endowment Fund, £2,151 11s. 3d. North British Railway, 3% Debenture Stock, £123 5s. 0d. New South Wales 3% Inscribed Stock, £100 0s. 0d. 5% War Loan 1929-47, £7 19s. 11d. cash.

Between the end of 1916 and August 7th, 1917, the following further donations have been received :—

	£	s.	d.
Col. H. Mellish (4th Don.)	50 0 0
R. Cooke, Esq. (8th Don.)	4 5 0
Under £2	1 0 0
			<hr/>
			£55 5 0
			<hr/>

Out of this sum and the balance at end of 1916, the £100 5% War Loan was applied for.

THE PRINCIPAL DONATIONS TO THE ENDOWMENT FUND RECEIVED UP TO AUGUST 7TH, 1917, WERE AS FOLLOWS :—

Boughton, Miss F. H. Rouse	£110
Brook, Charles L., Esq.	£500
Druce, Francis, Esq.	£200
Freshfield, D. W., Esq., D.C.L.	£200
Mellish, Lt.-Col. H., C.B.	£250
Morrison, W., Esq.	£215
Murray, the late Sir John, K.C.B., F.R.S.	£100

THE LATE SIR ALEXANDER BINNIE.By DR. H. R. MILL.

ALEXANDER RICHARDSON BINNIE was born in London on March 26th, 1839, educated at private schools and trained as a pupil of the famous civil engineer J. F. La Trobe Bateman. To him and to Terence Woulfe Flanagan, under whom he also worked as a young man, Binnie acknowledged his life-long indebtedness for a thorough grounding in his profession. He spent some time on Welsh railways, and in 1869, entered the Public Works Department in India, and in the larger field, amid the more intense forces of tropical Nature, he developed his powers and deepened his insight into the problems with which he had to deal. This was true especially of his study of rainfall, which was to bear fruit later in important generalizations. The chief work of Mr. Binnie during his six years in India was the construction of the Nagpore Water Works, his description of which won for him the Telford Medal of the Institution of Civil Engineers. On returning to England he filled the position of Water Engineer to the Corporation of Bradford, and had much interesting work in extending the water supply of that city. During the fifteen years of his stay in Bradford he continued the study of rainfall which he had commenced in India, and entered into his long connection with the work of the British Rainfall Organization. He set up a great number of new rain gauges, not only on the old gathering grounds, but in valleys as far afield as the Wharfe and Nidd. For this purpose he adopted the deep-rimmed 5-inch pattern of monthly gauge, which has since become widely known as the Bradford rain gauge.

In 1890 Mr. Binnie came to London as Chief Engineer of the London County Council, and although his duties were now much more varied than before he never lost interest in the study of rainfall. It was in 1892 that he read a most important paper to the Institution of Civil Engineers, entitled, "On mean or average annual rainfall and the fluctuations to which it is subject." This paper discussed a number of long rainfall records in all parts of the world, with the object of ascertaining first the length

of period necessary to yield an average which should represent the normal value of the average rainfall, and, second, the relation which years or groups of years of extreme rainfall bore to the average. One of the conclusions arrived at was that a period of more than 30 years was necessary to give an average not differing greatly from the average of a much longer period. Another that the wettest year in a long record might be as much as 151 per cent. of the average, while the driest year might be as little as 60 per cent. of the average. A third relation pointed out was that the mean rainfall of the driest three consecutive years was about 76 per cent. of the average annual rainfall. The relation which is taken as the basis of all calculations of the reservoir capacity required in order to utilize the rainfall of any particular area in the British Isles is 80 per cent., as suggested by Mr. Symons twenty-five years earlier, and the difference is less than one would expect, when the wider range of Mr. Binnie's investigations is considered.

The London County Council, as the Water Authority of the Metropolis before the formation of the Metropolitan Water Board, considered various schemes for increasing the supply, and their Engineer planned an extensive scheme in 1893 for obtaining water direct from the valleys of Wales. Under the supervision of Mr. Symons rain gauges were set up over a large part of Wales extending from the watershed of the Elan on the north to the basin of the Usk on the south. The utilization of the Welsh valleys for London water supply was a project very near to the heart of Sir Alexander Binnie, and his plans showed that an ample supply of the purest water from Wales could easily be obtained by gravitation. When the Metropolitan Water Board took over the responsibility for the supply of London the official observations of rainfall in Wales were stopped, and it was decided to continue to pump the water required from the Thames and Lea and from deep wells in the chalk.

Though Sir Alexander's name was destined not to be associated with London's water supply, it will always be connected with the improved drainage schemes for the London area, and in particular with the roadways under the Thames at Blackwall and Greenwich, where the river could not be bridged. The Blackwall Tunnel was opened in 1897, and Sir Alexander was knighted in the same year. He retired from official work in 1902, but, until a few years before his death, he practised as a consulting engineer at Westminster, establishing the firm of Binnie, Son, and Deacon, in partnership with Mr. W. J. E. Binnie (the inventor of a very ingenious

electrical recording rain gauge) and Mr. Martin Deacon, nephew of the late Dr. G. F. Deacon.

When Sir Alexander Binnie became President of the Institution of Civil Engineers in 1905, he delivered a remarkable address to the members, tracing the origin of civil engineering in England and contrasting the difficulties which pioneers such as Brindley, Smeaton, Watt, Rennie and Telford experienced in the early days of canals, roads and railways, with the advantages which professional training conferred on the young engineers of to-day. In this address he developed a favourite thought that the advance of civilization was bound up with the development of engineering science. In all his work he looked beyond the mere technical or local problems and drew inspiration from the wider outlook congenial to his philosophical turn of mind. In 1913 he published a book, entitled, "Rainfall, Reservoirs, and Water Supply," summarizing the outcome of his life-long experience.

Personally he had a remarkable geniality of manner and a calm, untroubled way of discussing the problems on which he was engaged, which made a consultation with him something to look forward to and remember. His wide experience in many lands and his sympathetic tolerance of views he did not himself hold, gave a special quality to his conversation as he sat wreathed in cigar-smoke, always busy but never in a hurry.

When Trustees were being selected to take over the British Rainfall Organization in 1910 he was the natural and inevitable choice as a representative of the engineering profession, and he readily accepted the responsibility and always continued to take a kindly interest in the development of the branch of science for which he had himself done so much.

ON AN IMPROVED METHOD OF FIXING RAIN GAUGES.

By SIR HERBERT GEORGE FORDHAM.

THE ordinary arrangement adopted for ensuring the stability of rain gauges when fixed in the open on a lawn or other natural surface seems to me by no means satisfactory, and an improved method seems worthy of description.

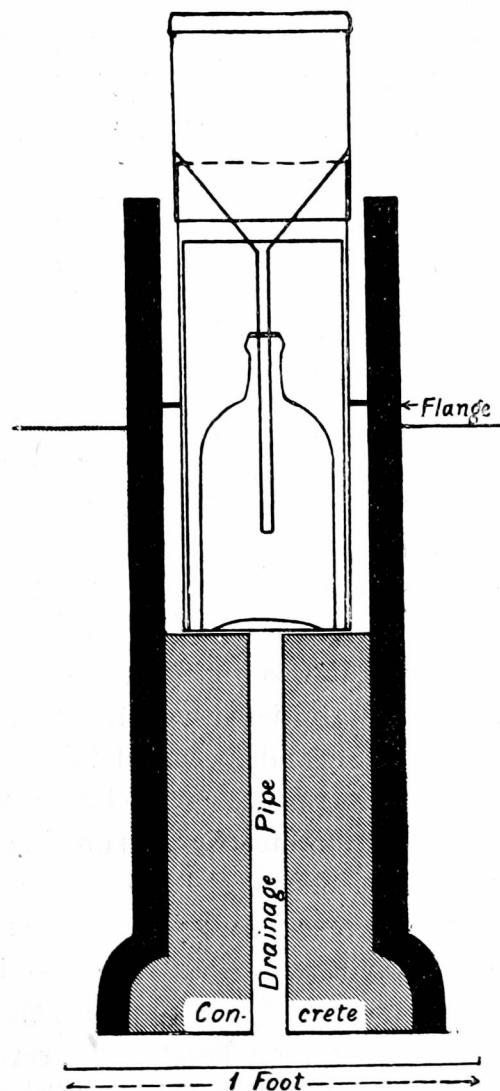

Some years ago I adopted an arrangement of a much more solid and permanent character, not involving much initial expenditure, which, on trial has been so satisfactory that I consider it suitable for general adoption. It may not be new, although I am not aware of its use elsewhere.

My method in fixing an ordinary 5-inch gauge is to select a well-shaped 6-inch glazed socket drain-pipe of the ordinary pattern and to fix it in the ground with the socket end downwards and the upper edge projecting about 6 inches above the surface level. About 10 inches of the bottom part of the upright pipe is filled in with cement concrete with a smooth horizontal cement top surface, upon which the gauge will stand when fixed. A drainage tube should pass through this concrete filling to take off any water which, running down the side of the gauge, might otherwise accumulate on the top of the concrete.

The stand for the gauge itself is now complete. It is so simple and solid that it may be expected to last for a very long period without movement or decay. The brown ware has a good appearance in association with the copper work of the gauge itself, its circular form adapts itself to the gauge, and it presents no angles for destruction by gardening tools carelessly used. All that is now necessary for fixing the gauge is the soldering on to the lower and fixed portion of the gauge itself of a thin projecting flange or rim of copper, at a few inches from its upper edge. This flange should be a trifle larger than the upper aperture of the drain-pipe as fixed, and should be reduced by filing so as *exactly* to fit the pipe and to adapt itself to any trifling irregularities of shape or surface in the

latter. By a little care, even if the drain-pipe itself is not absolutely regular in form or upright in the ground, the gauge can be thus fixed, once and for all, rigidly in its correct position.

This general plan is adaptable to the ordinary pattern of 5-inch Snowdon gauge, the height of the rim of the drain-pipe above ground, the level of the top surface of the concrete filling, and the position of the retaining copper rim being varied according to the dimensions of the gauge, receiver, etc. For a gauge of circular orifice of larger diameter, a drain-pipe of corresponding size would be chosen. The whole arrangement is shown in section to scale in the accompanying diagram.

THE SNOWSTORMS OF FEBRUARY AND MARCH, 1916.

By L. C. W. BONACINA.

IN the year 1916 conspicuous snowfall in the British Isles was confined to the months of February, March, and December. In February and March, 1916, the snowfall was exceptionally intense, and associated with somewhat unusual barometric conditions, and its effects are likely to be long remembered in many districts. Whilst the data available from the remarks of the Observers and from other sources are not sufficient to render a detailed study possible, they serve to supplement the general outline of information dealt with provisionally in *Symons's Meteorological Magazine* for April, 1916. (Vol. 51, p. 37).

Distribution :—After the break-up of the hard frost of November, 1915, snow was little in evidence during December, 1915, and almost entirely absent during January, 1916, a very rare event indeed. On this occasion, however, the balance of nature was quickly redressed, inasmuch as the severe snowstorms that followed at the end of the cold season will cause the year 1916 to stand out conspicuously in the meteorological annals of Great Britain. No sooner had February entered than the barometric depressions, which had for the most part taken a course well to the north of these islands during the exceptionally warm January, began to take a more southerly route, causing a rapid alternation between warm air currents from the south-west and cold winds from the west and north-west. These conditions prevailed throughout the first three weeks of February, and it was during the temporary predominance of the colder winds that intermittent snowfalls, locally very heavy in Scotland and the north of England, occurred fairly generally. Neither in intensity nor distribution were these snowstorms, which accompanied quite a common distribution of barometric pressure, in any sense abnormal. They proved to be the precursors of the intense snowstorms which characterized the ensuing six weeks, in accordance with the manner in which extreme types of weather conditions always seem to be introduced by a longer or shorter series of preliminary events on a smaller scale. About February 21st the pressure situation became the reverse of that which held in January, the highest barometer being in the north, thus setting

up a gradient for easterly winds over England. With this change the temperature dropped to the freezing point and during the last ten days of the month the whole of England, except the extreme north, was visited by a succession of heavy snowfalls, which were especially severe in the elevated regions of Dartmoor, Exmoor, the Cotteswolds, and the mountain ranges of Wales. With the arrival of March the most intense phase of the snow spell was over, so far as the greater part of England was concerned, but the snowstorms had extended to the north of England and south of Scotland, causing great accumulations and gigantic drifts in the Pennines and Southern Uplands. Although during the first three weeks of March the snowy easterly type of weather persistently held, a rise of temperature in the lowlands of England, occasioned by a complicated system of barometric depressions taking irregular courses in the neighbourhood of the English Channel, brought rain instead of snow in the south. It was only in the Uplands that the cold was great enough to cause the heavy precipitation during all this time to take the form of blizzards of snow—a prolonged succession of paralyzing snowstorms isolating moorland farms and villages, burying sheep, obliterating roads, and rendering unworkable for weeks such elevated railways as the High Peak of Derbyshire, and that further north over the Pennine chain connecting Kirkby Stephen, in Westmorland, with Barnard Castle, in Durham. During the first three weeks of March, therefore, the distribution of snowfall seems to have been distinctly orographic, *i.e.*, related to the height of the land. After March 25th a reversion to a more westerly type of conditions marked the final stage of the snow spell. A deep cyclonic depression in the north brought some heavy falls of snow in Scotland, whilst another small but deep depression moving across southern England on the 27th and 28th caused a destructive snow gale which uprooted countless elms and other trees and overthrew telegraph poles throughout much of the south-eastern part of England. Although this storm brought heavy snow locally it was more remarkable, on the whole, for wind than precipitation, and it proved to be the end of the long period of inclement weather. During the first half of April the weather continued rather bleak, but there was no significant snowfall in that month.

Depth :—Owing to the paucity of systematic records and to the fact that much of the snow which fell in March was of a wet character, soon melting, it is impracticable to give any cartographical representation of either aggregate or actual depths of snow such as would serve any useful

purpose ; but from such material as has been supplied to the British Rainfall Organization, from information given in the Weather Reports of the Meteorological Office, and from newspapers and other sources, it can be stated with some confidence that over much of the lowlands of England the aggregate of the numerous heavy and light falls during the two months amounted to as much as 3 feet, and that in some of the mountainous regions of England, Wales and the south of Scotland to as much as 10 feet, the difference being attributable partly to the lower temperature in the highlands and partly to heavier precipitation in those regions. Owing to the frequent thaws preventing accumulation the actual depths of snow recorded at any time as lying in the lowland districts bear, on the whole, a rather small ratio to the high aggregate figures for the whole period just quoted. But there were at times some thick coverings, and it would be near the truth to say that during the last week of February, when the snowfalls were fairly dry, the average depth of snow lying over England was 8 inches, with considerable variation from place to place. As regards the hill districts there seems to be little doubt that in the Welsh mountain ranges, the elevated moorlands of the Devonian peninsula, the Pennine chain and southern Scottish uplands, snow at times was lying 2 to 5 feet deep, whilst drifts estimated at from "20 to 50 feet" are frequently referred to in the reports. In the Black Mountains of Brecon the snowstorms appear to have been extremely severe, and Mr. Gethin Jones, who has had unrivalled experience, estimates the depth of snow lying on the hills in March at nearly 5 feet, the last drifts not disappearing till a burst of summer heat set in towards the end of May. For the whole period he estimates the aggregate snowfall in the district at some 10 feet, of which 8 feet fell in less than three weeks, between February 20th and March 11th, a rate of fall apparently as great as normally occurs in the excessively snowy mountain ranges of western North America. At Wearhead, in the Pennines, at an elevation just over 1,000 feet, the melted snowfall for March is given as 9.96 in., which, on the assumption that nearly all the moisture really did fall as snow, means a depth of some 10 feet of snow in the aggregate ; at any rate it is stated that the "worst snowstorm for thirty years continued throughout the month." Further light on the relation of the Pennine chain to the snowfall in March seems to be thrown by the rainfall map of the British Isles for March, 1916.* On this map the position and shape of

* See page [76].

the Pennine range is clearly delineated by an area of general precipitation of 4 to 6 inches of rain, *i.e.*, 4 to 6 feet of snow in the aggregate ; and it is interesting to note that the country lying west of the Pennines, that is to leeward of the prevailing easterly wind, was much drier than that lying to the east. At all events it seems probable that taking the month of March, as a whole, the Lake District mountain group, shielded by the Pennines, suffered comparatively little from the snowstorms ; and similarly it would not appear that the Snowdon block in North Wales experienced the same intensity of snowfall as the more southern Welsh ranges like the Black Mountains, unprotected by very high ground to the east. There are certainly indications that in March, 1916, the Pennine uplands threw a decided "snow-shadow." On the Dartmoor plateau, in Devonshire, where snowstorms, if less frequent on the average of years than on the north-country fells, occur at times with formidable severity, snow-drifts 10 feet in depth were very common in March, and the snowstorms between February 21st and March 27th, 1916, were recorded as the greatest since the tremendous blizzard of March, 1891, when all the snow came down in three days. It should not be forgotten, however, that other bad months have occurred in the interim, and Dartmoor was snow-bound pretty badly in the March of 1901. As to how the Scottish Highlands fared during the snow period of 1916 it is difficult to speak definitely, owing to the scantiness of data. Although heavy falls occurred in the earlier part of February there seems no ground to suppose that the Grampian mountain system, normally the snowiest portion of the kingdom, experienced the same intensity of weather as the uplands in the south of Scotland and north of England, and the general character of the weather in March was drier in Scotland than in England. There is very little information about the depth of the snowfalls in Ireland, but there can be no doubt that the western isle suffered far less than Great Britain in February and March, 1916.

In the London district the aggregate snowfall for the period was at least 2 feet, and along the northern heights at Hampstead it was nearer 3 feet, or more snow than had fallen at any time since March, 1909, when, however, the intense cold allowed deeper accumulations.

Considered as a snow-spell of more than a week's duration, affecting the whole country, it would appear that the period of six weeks in 1916 was the most intense since the three weeks January 26th to February 16th, 1900, excepting possibly February 26th to March 16th, 1909.

THE MEASUREMENT OF RAINFALL DURATION.*

By CARLE SALTER.

THE desirability of obtaining accurate measurements of the duration of rainfall as a supplement to records of its amount is sufficiently obvious, for until some information of the kind became available our ideas of rainfall frequency were dependent upon statistics of the number of rain days, a notoriously broken reed, or upon rough, non-instrumental estimates of rainfall duration, which could hardly be regarded as scientific observations. The value of recording the duration of sunshine as an element of climate has long been recognized, and sufficient data have been collected to enable maps of the normal distribution to be constructed. There seems no adequate reason why the systematic recording of rainfall duration should not be developed on similar lines.

Both Mr. Symons and Mr. Gaster, more than fifty years ago, referred to the desirability of obtaining records, and in 1869 Mr. F. E. Sawyer brought together a few non-instrumental records of duration made at Brighton and at Bogside, in Aberdeenshire.† All other early references to so-called rainfall duration appear to be based merely upon frequency values deduced from hourly observations. A great deal of ingenuity was expended during the latter half of the nineteenth century in devising various forms of automatic rain gauges, and it is curious to find that their records were apparently not used for this elementary purpose. In 1880, however, Mr. Baldwin Latham published in *British Rainfall* a series of records of measured duration at Croydon, and these records were continued without a break till 1916. These probably rank as the earliest observations in any way comparable with modern duration records. In 1903 the records of a self-recording gauge established at Seathwaite by Mr. Symons were discussed in a paper by Dr. H. R. Mill read to the British

* Abstract of a paper published in the *Quarterly Journal of the Royal Meteorological Society*, Vol. xlvi. No. 181. January, 1917.

Association at Southport in 1903. A second paper on the same subject was read before the Royal Meteorological Society in April, 1905.*

DISTRIBUTION OF STATIONS RECORDING DURATION OF RAINFALL UP TO THE END OF 1915.

Block kindly lent by the Royal Meteorological Society.

* Q.J.R. Met.Soc., Vol. xxxi., 1905, p. 229.

In 1904 Dr. Mill made an analysis of the traces from the Casella Standard gauge at Camden Square from 1881 to 1904, and published the results *in extenso*, in *British Rainfall, 1904*. In the volume for the previous year a section was devoted for the first time to records of measured duration. The number of records received grew very slowly, and five years later *British Rainfall, 1908*, contained only ten, but the introduction of less expensive self-registering rain gauges during the last few years has provided a stimulus, and in *British Rainfall, 1915*, the number had grown to 48 records.

The accompanying map shows how far these records, and others now discontinued, give any representation of the varied climates of the British Isles. The approximate position of each station is shown by a round dot, or by a triangle if the record is no longer kept up. The total number of stations for which any information had been received up to 1915 was 58.

The whole of these records, with the exception of one or two which were received too late, have been published year by year in *British Rainfall* and form a nucleus from which valuable climatological information may be deduced, but the present paper deals rather with the methods, and preliminary difficulties encountered, than with the results, except in so far as the latter illustrate the former.

In all the types of self-registering rain gauge employed for measuring rainfall duration the record is traced on a drum by an integrating curve which indicates the intensity of the rainfall by its inclination to the horizontal lines on the chart. When rain is not falling the pen travels parallel to the base line. In order to obtain a measurement of the duration of rainfall for the period covered by the chart all that is required is to measure the periods during which the trace is not parallel to the base line in terms of the time-scale of the chart, the result being expressed in hours and tenths of an hour. In order to get results of any value the drum of the gauge should make a complete revolution every 24 hours; in gauges with drums revolving only once in a week the scale is too restricted for accurate measurement. It is also important that the trace should be a continuous line. Gauges of the "step-by-step" type, recording each .01 in. or .005 in. by a separate vertical movement of the pen, give good enough results when rain is falling heavily and continuously, but give no indication of the true duration during light rain. In placing the chart on the drum of any self-registering gauge very great

care must be taken to set it perfectly straight ; otherwise the pen will trace a line at a slight inclination to the base line when no rain is falling, and even if rain is falling the degree of the inclination will be affected.

No self-recording rain gauge will work well and consistently without constant care and attention. Any friction in the working parts may cause it to give seriously erroneous results. As an example of this, in gauges of the float type, where the pen is actuated by the movement of a float which rises as the rain enters the receiver, should there be any tendency for the float-guides to jam, the pen shows no vertical movement till the pressure of the water becomes great enough to overcome the resistance, and when this happens it rises with a jerk, so that the slow and steady rain of an hour may be recorded as if it had fallen in a minute. In the record of the amount of rain registered this causes no error, but in the record of duration the error is liable to be large. Proper lubrication * of the working parts prevents this type of failure.

In order that there may be no break in the record during snow, some means must be introduced to melt snow as it falls so that it shall not accumulate in the funnel of the gauge. In some gauges a small paraffin lamp is used, but a night-light is usually sufficient and is less liable to over-heat the gauge and give rise to evaporation.

It is strongly recommended that an ordinary direct-reading rain gauge should always be placed alongside a self-registering gauge as a check, and if the two show any appreciable difference in the amount recorded the latter should be overhauled. Faulty recording usually arises from unequal wearing of some part of the mechanism, or from clogging due to dust adhering to dried oil.

In case of any failure or partial failure of the gauge, the duration should be interpolated as far as possible by eye observation and it is therefore advisable, if possible, to compute durations day by day rather than to allow charts to accumulate till the end of the month or year when the particular circumstances may have been forgotten.

Given a suitable self-recording rain guage properly handled, it is a very simple matter to measure the duration during heavy or moderately heavy rain. With very light rain, however, and it must be remembered that from the point of view of duration the very light rain forms a large fraction of the whole, the element of personal equation comes into play.

* Either by clock oil or graphite.

Observers are asked to include in the duration total all periods when the curve is perceptibly rising ; but what is perceptible to one person may be imperceptible to another, and there is no doubt that some of the inconsistencies in duration records can be attributed to this cause. A close analogy occurs in the measurement of the duration of sunshine but the discrepancies are probably larger in the case of rainfall duration.

The personal element is, however, not the sole source of trouble. The improvements which have been introduced in self-registering rain gauges in the last few years have nearly all tended towards producing an instrument of higher sensitiveness, so that if we compare, for example, the traces of the old Casella Standard with those of Baxendell's new "Fernley," or improved "Halliwell" gauge, it is obvious at once that whilst the Fernley is capable of recording rain hardly more intense than a Scotch mist, the older gauge requires distinctly heavier rain to set it in motion. To take an extreme instance, therefore, we might quite possibly have the case of a day, such as sometimes occurs, when precipitation is quite perceptible for many hours, but so light that it produces only a few drops in the rain gauge. In such circumstances the Fernley may show a slow gradual rise of the curve, quite distinguishable on its very open-scale chart, and a duration of 10 or 12 hours, whilst the less sensitive gauge records a day of no rain. If the duration is measured in one case as 12 hours and in the other as 0, we have the elements of a discrepancy of the first magnitude.

There are not many data upon which to base a comparison between the results from different types of self-registering rain gauges, because for this purpose it is necessary that two or more gauges should have been maintained side by side for a considerable period and the curves measured by the same computer. Valuable records of this kind have been kept during the last few years by Mr. A. J. Walker, of Thirsk, who has at present four gauges of different patterns at work. Two of these, a Halliwell and a Hyetograph, are among the most widely used instruments.* These records cover a period of 17 months up to the end of 1915. A Halliwell and a Hyetograph were also used simultaneously at Aberclyd, in Breconshire, for three months in 1912, and provide interesting confirmation. The following table gives the comparative results. The observations are grouped in three-monthly periods because the relation appears to differ at different seasons : in individual months rather greater variations are sometimes found.

* A full description of these two gauges is given in *British Rainfall*, 1908, pp. 22-27

Comparison of Rainfall Duration from Halliwell and Hyetograph Gauges.

THIRSK.				ABERCLYD.					
Period.	Rain-fall.	Duration.			Period.	Rain-fall.	Duration.		
		Halli-well (A.)	Hyeto-graph (B.)	B as percent- age of A.			Halli-well (A.)	Hyeto-graph (B.)	B as percent- age of A.
1914.					1912.				
Aug.-Sep. ..	3.08	49.9	44.8	90	Jan.-Mar. ..	20.72	516.5	451.9	88
Oct.-Dec. ..	9.72	237.8	210.2	88	Apr.-June ..	2.73	77.3	75.7	98
1915.					July-Sep. ..	8.16	127.1	116.2	91
Jan.-Mar. ..	8.30	255.5	229.0	90	Oct.-Dec. ..	8.06	218.6	197.0	90
Winter	26.08	711.9	636.2	89	Winter ..	20.72	516.5	451.9	88
Summer	13.97	254.3	236.7	93
Total	40.05	966.2	872.9	90

The periods are too short to give conclusive results, but there is a suggestive consistency. The durations for the two gauges agree more closely in summer than in winter, a result no doubt due to the greater prevalence of rainfall of very small intensity in winter. It is not impossible that some of the disparity may arise from unequal loss by evaporation in the two gauges. The Halliwell is certainly much more air-tight than the Hyetograph, and the air space within the cover is considerably smaller.* A variation of 10 per cent. between the records of two of the most widely used self-recording gauges is not a matter to be ignored, and points to the necessity of finding some means of comparing the results from other patterns.

If we take the records from 48 stations published in *British Rainfall, 1915*, the correlation co-efficient between the rainfall amount and duration is +0.80 with a probable error of 0.04. Correlating the total rainfall of each year at Camden Square back to 1881 with the total duration, the coefficient and probable error give an identical result, +0.80 and 0.04. This shows clearly that there is a close relationship between the amount and the duration. On the other hand, correlating the *mean rate of fall per hour* with the total rainfall for the 1915 records the coefficient is only +0.32 with a probable error of 0.09, and for the 34 years at Camden Square the coefficient is 0.00 with a probable error of 0.12, showing

* Mr. Halliwell attributes the difference not to the air space, but to the fact that in the Hyetograph the ratio of the collecting area of the funnel to the wetted surface is 20:100, whilst in the Halliwell it is 30:100.

that the distribution and incidence of mean rainfall intensity is dissimilar to that of total rainfall. Plotting the mean rain per hour for each station for any year on a map, there appears to be no geographical relationship between the intensity figures, and the differences between adjacent stations are frequently larger than the differences between stations of quite different climate. For instance, Kew and New Malden, about 5 miles apart, and with no appreciable difference of climate, give, in 1915, .069 in. and .042 in. per hour, respectively, whilst Kinlochleven, in the West Highlands and Huddersfield, with entirely different climates, give .046 in. and .047 in., respectively. Grouping the values of rate per hour for 1915 according to the pattern of gauge indicates that the value is in some measure dictated by the kind of instrument used.

Mean Rate of Rain per Hour in 1915.

Pattern of Gauge.	Number of Records.	Mean. in.	Highest. in.	Lowest. in.
New Casella Recorder	3	.045	.048	.042
Halliwell	6	.050	.061	.040
Hyetograph	22	.050	.063	.040
Beckley	6	.064	.078	.054

Out of the 22 Hyetographs 13 give values below .050 in. and only one above .060 in. The three new Casella Recorders all give low values, whereas the Beckley figures are all high. The mean value for the Hyetographs agrees with that for the Halliwells, which is not what one is led to expect from the detailed comparisons at Thirsk and Aberclyd. A high rate per hour of course indicates a relatively low duration, and the main conclusion we are able to deduce is that, generally speaking, the new Casella Recorder yields the largest duration values and the Beckley the smallest among the gauges represented.

The problem of standardizing rainfall duration records is one of peculiar difficulty. A solution might be found either in insisting on a standard type of instrument or in a modification of the method of measuring the traces. If we desire to adopt the latter course, it is clear that since one gauge will register in very light rain, whilst another will not do so, we must either leave the very light rain out of account altogether or place it in a different category. A great many very tedious experiments would be necessary in order to hit upon a suitable minimum intensity below which the duration of rain should be excluded. If this is put too low

it will fail in its object ; if too high, we run a risk of getting a false impression of the prevalence of very light rainfall and its geographical distribution. A test is provided by an analysis of the Halliwell and Hyetograph traces made at Thirsk in 1915, measuring the total visible duration and, separately, the duration exceeding the rate of .01 in. in 3 hours (0.1 mm. per hour). This limit was selected as likely to be perceptible in almost any kind of gauge, and yet a rate below which rainfall is not of any practical importance. The records at Aberclyd for 3 months in 1912 were also analysed in the same way and gave generally confirmatory results, and further general confirmation was obtained from an examination of the Camden Square records.

Period.	Rain- fall. in.	Total Duration.			Duration above .003 in. per hour.			Duration above .003 in. per hour as per- centage of Total Duration.

Total	27.25	678.5	617.9	91	602.3	564.2	94	89	91

The results show that, although on the whole year the records from the two gauges are brought slightly more into accord, during part of the period the disparity is even increased by omitting the very light rain. On the whole year the duration is reduced by 11 per cent. for the Halliwell and by 9 per cent. for the Hyetograph. This appears to indicate that, whilst the limit tentatively selected is high enough to affect the duration values by 10 per cent., it is considerably too low to eliminate the original discrepancy between the results for the two gauges.

As mentioned above, we are still much in the dark as to the relative loss by evaporation in the two gauges. It is possible that this may be considerable even in winter, since the risk of snow falling at Thirsk is sufficiently great to make it necessary to keep a lamp burning in the gauge on a large number of days.

In comparing the records of two gauges like the Halliwell and Hyetograph, it must be borne in mind that sensitiveness in recording light

rainfall is not the only desideratum in a self-recording instrument, and that the very small number of failures to record with the Hyetograph, compared with almost any other pattern, give this instrument some great advantages.

So little has been written on the subject of rainfall duration, and it appears so well worthy of the attention of meteorologists, that it is to be hoped that in the near future the preliminary obstacles to which attention has been drawn may be cleared away. When that has been accomplished, the element of rainfall duration may take its proper place among the recognized factors of climate, where it has an importance equal to that of the duration of sunshine.

THE STAFF OF OBSERVERS.

WHEN the most rapid extension in the number of rainfall Observers was taking place at the beginning of the present decade each successive volume contained nearly 200 more records than its predecessor, 200 old records disappearing and 400 new records finding a place. In 1913 various causes led to the increase dropping back to what might be looked upon as the normal figure of about 100, and when after the outbreak of the war the annual increase was 83 for 1914, it could hardly be said that the depression was appreciable. In 1915, however, the usual gain was changed to a net loss of 41, and as the effect of the continuance of the war on affairs at home is cumulative, we are not surprised to find that the returns sent in for 1916 are 220 fewer than in the previous year. We are of opinion that many records which have not reached us are still being continued, as we know of instances in which corporations have been unable on account of reduced staff to have the figures copied out. We have also heard of instances in which private Observers have mislaid the 1916 figures, and we think that these are representative rather than exceptional cases.

Accordingly we have not attempted to analyze the gains and losses in the usual way this year, as we cannot distinguish the temporary from

Year.	Total Gain.	Returned.	Real Gain.	Total Loss.	Temporary.	Real Loss.	Net Real Gain.
1906.....	400	58	342	237	40	197	145
1907.....	375	49	326	289	81	208	118
1908.....	444	62	382	251	64	187	195
1909.....	426	89	337	290	87	203	134
1910.....	490	81	409	292	73	219	190
1911.....	502	99	403	304	94	210	193
1912.....	498	81	417	300	120	180	237
1913.....	456	58	348	308	140	168	180
1914.....	432	77	355	349	157	191	164
1915.....	433	89	344	474	183	291	53
1916.....	290	510

the permanent losses without an amount of correspondence that would be troublesome to Observers who are engaged on public work and altogether out of proportion to the value of the information when obtained. We therefore content ourselves with the statement that 290 records in this volume did not appear in 1915, and that 510 which appeared in that year

are absent. The following summary shows how the different countries were affected, and details for the individual counties appear in the condensed table of gains and losses. It may be pointed out that the loss of 220 stations corresponds only to 4 per cent. of the whole number, and that the only years in which a larger number of records has appeared are 1912 to 1915. A few remarks of a less general character may be of interest :—

1916.	Total Gain.	Total Loss.	Difference.	Per cent. decrease.
England	209	380	—171	4·1
Wales	26	34	— 8	1·8
Scotland	41	63	— 22	2·8
Ireland	14	33	— 19	6·6
British Isles	290	510	—220	4·1

England showed an increase in four counties and no diminution in five ; but the falling off was serious in twelve counties. This was by no means worst on the east coast, so that the fear of hostile raids cannot be held responsible. Norfolk and Suffolk were bad, but Essex was very good, showing a net increase of 3 stations, and Lincolnshire showed little loss, while Cambridgeshire had only 1 gain to set against 12 losses, being nearly the worst affected county in the British Isles. The extreme western counties and several in the Midlands showed many losses, but no geographical grouping can be made out. In the north, Cheshire had deplorable losses, but Lancashire had a loss of only 1 ; the North Riding of Yorkshire lost 9, while Durham showed a gain of 1 record. The whole loss in England was 4 per cent. of the 1915 number.

Wales, but for Breconshire, where the stations are 8 fewer than last year, would have shown very little change for the worse, and we hope that many of the missing records have not stopped ; as it is, the number of stations is only 2 per cent. less than last year.

Scotland, which, in the second year of the war continued to improve in the number of rainfall records, now shows a loss of 3 per cent. of the 1915 returns. This is almost entirely due to two large groups of gauges kept by public bodies, which many applications failed to secure. The gauges were duly read and these are the only groups of records kept by public authorities in the British Isles which have not been sent in. The worst losses are in Inverness-shire. We note with pleasure an improvement in the south of Scotland, especially in Midlothian.

Ireland retains its old character for steadiness in rainfall work, no less than 12 counties out of the 33 show neither a gain nor loss as com-

pared with last year, and in 2 more the gains balanced the losses. Three counties, *ciz.*, Kerry, King's County and Down, show a marked improvement, with practically no loss, and only four, Clare, Wicklow, Dublin and Fermanagh, are seriously worse than last year; but there are so few rainfall stations in Ireland that the net loss of 19 amounts to $6\frac{1}{2}$ per cent. of the total number in 1915.

Number of complete rainfall records published in the volumes of British Rainfall for the undermentioned years.

Years.	England.	Wales.	Scotland.	Ireland.	British Isles.	Change from previous years.	No. of Stations per 100 sq. mi.

In the lists the figures following the name of each county indicate the numbers of records lost and gained, the total number appearing in *British Rainfall* 1916, and in heavy type the number of records per 100 square miles of area. The letter *a* stands for the number printed in 1915. In the County of London for example *a-6+4=77...66* means that 6 of the records printed in 1915 are not available in 1916 whilst 4 new records appear, making the total number 77, or 66 per 100 square miles of area within the county.

OBITUARY.

By a series of coincidences the number of Observers whose names have to be included in the list of deaths for the twelve months ending June 30th, 1917, is 92, the same as last year, and we have been able to ascertain the ages of 67 of these, also the same number as last year. The average age was 72, the same as last year, and 19 had attained the age of 80 or over, again the same as last year, while 3 of these, as against 4 last year, were 90 years old or more. The final coincidence is that only 3, as last year, were less than 40. So far as we have been able to ascertain only 4 Observers were killed in action during the year, the small number being accounted for by the fact that very few of the rainfall Observers reporting to us are under military age, and a comparatively large proportion of those few are unfit for military service. We omit this year the list of octogenarians amongst the Observers who died during the year, but we add the age where it has been ascertained to the names in the general list, in which those who have fallen in the war are indicated by a special mark. The following list includes the names of those Observers whose records extended over 30 years or more. It is much shorter than last year's list, but it is remarkable in containing no less than five, with a record of half a century or upwards, and one, Mr. J. W. Robson, of Dalton, Huddersfield, whose record extends to 60 years, although it did not appear in

Records of thirty years and upwards.

Mr. J. W. Robson	60 years	Mr. E. Mawley (75)	44 years
Mr. W. R. Nash (82)	57 ..	Mr. Baldwin Latham (81)	41 ..

Mr. R. Gordon	45 ..	Mr. W. B. Butler (60)	31 ..

British Rainfall until 1865. The necessity for reducing the size of this volume compels us with much regret to restrict the biographical notices, and we are obliged to confine ourselves to the following brief epitome of the more notable services rendered by our old friends and colleagues.

A full notice, accompanied by a portrait, of SIR ALEXANDER BINNIE, a Trustee of the British Rainfall Organization, appears as the first article in this volume, and we refer to Symons's *Meteorological Magazine* for particulars regarding three past Presidents of the Royal Meteorological Society, all of them old Observers and life-long friends of the Organization. They are :—MR. W. ELLIS, F.R.S. (*Met. Mag.*, January, 1917), MR. BALDWIN LATHAM (*Met. Mag.*, June, 1917), and MR. EDWARD MAWLEY (*Met. Mag.*, October, 1916), and to these we must add MR. WILLIAM MARRIOTT (*Met. Mag.*, January, 1917), so well known as the Assistant Secretary of the Royal Meteorological Society, whose services in training Observers were unsurpassed.

CAPTAIN REX W. BIRD, who was killed in action at the age of 23, ceased observing when he joined the Army in October, 1914, as a private in the Bristol Battalion. He received a commission in the Wilts Regiment in January, 1915, and after seeing much service at the Front, during which he was wounded, was promoted in December, 1916. Though trained as an architect he developed a genius for leading men, and nobly upheld the finest traditions of the Army.

MR. W. B. BUTLER, of Old Southgate, was one of the most enthusiastic meteorological Observers who ever contributed to our pages. He not only kept continuous records at his residence for 31 years, but he equipped himself with a series of traveller's instruments, including a 3-inch Snowdon-Howard rain gauge and a miniature 1-inch copper Snowdon rain gauge, with a measuring glass to match. These and other interesting instruments, together with a legacy of £100, were left by Mr. Butler to the British Rainfall Organization, and the instruments will be preserved at 62, Camden Square, where they may perhaps form the nucleus of a rainfall museum.

LIEUTENANT H. S. HAWORTH, Yorkshire Light Infantry, was killed in action ten days after going to the front. From his boyhood he had been a keen Observer, and his records of rainfall and evaporation at Wakefield appeared in *British Rainfall* for many years.

MR. COLIN LIVINGSTONE, J.P., was a fine example of the old class of cultured and broad-minded parish schoolmasters in Scotland, and when he retired in 1894, he continued to devote himself to the scientific studies which he had pursued from his student days. He resided at Fort William for fifty years, and his meteorological record was established long before the idea of an Observatory on Ben Nevis took shape. Mr. Livingstone

assisted in the preliminary work of establishing the Observatory in 1883, and his exact local knowledge enabled him to plan the bridle path to the summit, which was traversed by many a meteorological pilgrim during the next twenty years.

MR. W. R. NASH, J.P., of The Mount, Carke-in-Cartmel, was an Observer of rainfall for 57 years, although, as in the case of the late Mr. J. W. Robson, his record did not happen to appear in the first volume of *British Rainfall*. Mr. Nash, like so many other members of the Society of Friends, had a remarkable aptitude for weather lore, and he made a life-long study of the southern margin of the Lake District. He was one of the founders of the Furness and South Cumberland Building Society, in 1865, and was, we believe, the Secretary of the Society from that time until his death. This gave him an extraordinarily detailed knowledge of his district, and he was ever foremost in every work of public utility.

THE REV. O. PICKARD-CAMBRIDGE, F.R.S., of Bloxworth, Wareham, was the leading authority on spiders, on which group he published several monographs of high value. He was also a devoted student of entomology, and he was a rainfall Observer for 32 years.

THE REV. J. C. ROSS, of Wadworth Hall, Doncaster, kept a continuous record of rainfall for 36 years, and probably derived his interest in this study from his father, the famous Arctic and Antarctic explorer, Sir James Clark Ross; the latter, it may be noted, when describing a heavy fall of rain at Sydney, N.S.W., mentioned that on August 1st, 1846, above 4 inches of rain fell between 3.30 p.m. and 6.30 p.m. in London, a record of which we have found no other trace.

MR. GEORGE SEARLE, of Edith Road, West Kensington, was the most scrupulous rainfall Observer we ever met, and devoted an extraordinary amount of care and attention to his instruments and their records. He took a great interest in the affairs of the Organization, and frequently presented books to the library, and on his death he bequeathed a legacy of £200 to the Endowment Fund.

MR. H. W. WALBANK, of Usworth Central Council School, Co. Durham, employed the rain gauge as a means of education with remarkable originality and success. Having visited his school and seen the interest which the pupils took in the records we persuaded Mr. Walbank to write a short description of his methods, which was published in *Symons's Meteorological Magazine* for 1909, Vol. 44, pp. 127-128.

MR. W. W. WILLMOTT, of Cleveland Parade, Darlington, came of a Quaker stock, and acquired from his father, Dr. A. T. Willmott, of Ross, Herefordshire, a love of nature, which he developed, especially in the direction of botany and conchology. For some time he kept a private school in Darlington, but for the greater part of his life he was in business continuing at work to the last to fill the place of those called to the war. His fatal illness was induced by patriotic over-exertion in his garden, and the day before his death he was eagerly discussing that morning's rainfall.

Observers deceased to June 30th, 1917.

Small Capitals designate Observers with records of 30 years and upwards.

Bailey, Richard Crawshay	Bodenham, Hereford.
Bates, Gilbert Thompson (70)	Mells Park, Frome.

White, John Newsom (73)	Rocklands, Waterford.
Wiggin, Sir Henry Arthur, Bart. (65)	Walton Hall, Eccleshall.
*Willmott, Walter Wade (81)	Cleveland Parade, Darlington.
Willson, Rev. Vere Francis (63)	Rauceby Hall, Lincs.
Woodhams, F.	Meopham, Kent.

BRITISH RAINFALL 1916.

PART II.

RAINFALL AND METEOROLOGY

OF

1916.

EVAPORATION AND PERCOLATION IN 1916.

THE death of Mr. E. Mawley, of Berkhamsted, and of Mr. Baldwin Latham, of Croydon, has taken away two of the six Observers of Percolation. One of Mr. Latham's two records, and also his evaporation results, for 1916, were however complete and appear, we fear, for the last time. There is no change in the main table of Evaporation records except that the observations at Worstead came to an end during the summer.

The year was one of moderate evaporation, principally owing to the cool moist weather of the summer months.

Evaporation at Camden Square, 1885–1916.

These Tables of meteorological observations are compiled from the readings taken at 9 a.m. and 9 p.m. The average, when quoted, is in every case for the 50 years 1860-1909. The rainfall is from the 8-inch rain gauge of the Meteorological Office pattern ; the radiation temperature from a black-bulb maximum thermometer *in vacuo* at a height of 4 feet above the ground, and from a link-bulb minimum thermometer laid on short

grass and freely exposed to the sky. The radio-integrator was described in *British Rainfall, 1907*, p. 44. Earth temperature is taken by spirit thermometers suspended in iron tubes of 1 inch internal diameter driven into the soil. They are read once daily at 9 a.m. The shade temperature is from thermometers on a Glaisher stand, the mean daily temperature being the mean of the maximum, minimum, 9 a.m., and 9 p.m. readings.

NOTE.—C indicates condensation.

THE DISTRIBUTION OF RAINFALL IN TIME.

THE arrangement of the sections of *British Rainfall* falling under this heading has been fully described in recent volumes, and this year we need not do more than remind our readers that the frequency and incidence of rainfall during the year, as shown by the number of Rain Days and the occurrence of definite spells of dry and wet weather, are dealt with by means of a detailed examination of 100 carefully selected daily rainfall records, representing all parts of the British Isles. The sections on Duration of Rainfall, and Heavy Falls of Rain in Short Periods, during 1916, on the other hand, include all the information on those subjects which has come into our hands.

RAIN DAYS IN 1916.

A RAIN DAY is a period of twenty-four hours ending at 9 a.m. in which .01 in. of rain or more is recorded, when readings are made to the nearest hundredth of an inch. Any fall greater than half a hundredth is treated as one hundredth ; any fall less than half a hundredth is ignored.

The number of rain days in 1916 as shown in the Table was above the average in all parts of the British Isles, least so probably in the southwest of England, and the west of Scotland, and most so in the east of Great Britain. More than 250 rain days occurred in the western counties of Ireland, in the Outer Hebrides, and the extreme north-west of Scotland. An isolated area in Argyllshire and a small patch in the English Lake District also had more than 250 rain days.

The number of rain days exceeded 225 in Ireland, except in the south and east, from Cape Clear to Donaghadee ; and in Scotland, save for two large areas, one running inland from the Moray Firth, the other extending along the whole east coast south of Aberdeen and inland as far as Blair Atholl and Bathgate. More than 225 rain days also occurred in the English Lake District and along the centre of the Pennine Chain as far south as

Buxton, as well as in the centre of Wales. The rest of England and Wales had fewer than 225 rain days and a large area in the south-east of England had less than 200 rain days, while part of East Anglia had fewer than 175. Parts of the coast of the Irish Sea, especially in the south-east of Ireland and around the Mersey, and a small area on the Moray Firth also had less than 200 rain days.

In order to save space we omit the usual maps showing the distribution of rain days in the year and in an average year. The statistical tables are, however, given in full so that continuity is preserved with previous years. Table I. gives the number of rain days in each month at each of the selected stations, and the mean values from this table enable us to compare the frequency of rain days during 1916 with the average general values for the countries and with each year back to 1903. From Table II. it will be seen that over the country as a whole there were 220 rain days, giving an excess of 16 rain days, or 8 per cent., over the average. The excess was greatest, 18 days, or 10 per cent., in England and Wales, being 16, or 7 per cent., both in Scotland and Ireland. Only two years in the fourteen under review had more rain days, *viz.*, 1903, with 229 days, or 112 per cent. of the average, and 1912, with 222 or 109 per cent. In England and Wales, 1910, and in Ireland, 1907, had slightly more rain days than 1916, but 1903 was the only year with larger general values for all the great divisions of the United Kingdom.

No satisfactory average monthly values have been worked out, and it is therefore impossible to state definitely the periods during which the frequency of rain days was most abnormal. The first two and last three months of the year had 20 or more rain days each, over the country as a whole, the largest number, 25, occurring in October. In Ireland the general number of rain days in this month was 28, many stations in the west having rain on every day. February ranked second in regard to frequency of rain days, having 22 rain days over the country as a whole. The general excess was due however less to a very high rain frequency in the winter months than to a persistent, though not extremely high, frequency throughout the summer half-year. No month, over the country as a whole, had less than 13 rain days, and only July and September had less than 15. Parts of England, Wales and Ireland had rather less than 10 rain days in July, but it is probable that with this small exception rain days were not less numerous than the normal in any part of the British Isles in any month of the year.

DROUGHTS IN 1916.

DROUGHTS of two classes are dealt with :—

THE ABSOLUTE DROUGHT is a period of *more than* 14 consecutive days no one of which is a rain day.

THE PARTIAL DROUGHT is a period of *more than* 28 consecutive days, the mean rainfall of which does not exceed .01 in. per day.

The records of the hundred stations utilized in discussing the number of rain days (*ante pp. [13-15]*) have been examined for droughts, and the results compared with similar data for each year since 1886 are set out in the following summary. In 1916 absolute droughts did not occur at 51 stations, practically the average number, and the 49 stations between them reported 52 droughts, or 14 less than the average; only three stations, two on the east coast and one in Anglesey, recorded two. The mean duration of the droughts was 20 days, or 2 days longer than the average.

There really was only one absolute drought, 45 instances being reported in the latter half of July and the earlier half of August; but the shortage of rain at this period was unusually widespread, being general over England and Wales south of Yorkshire, and also over the south of Ireland

and the Irish Sea. The drought began in most places between July 17th and 22nd, but, in a few, as early as July 12th. It lasted as a rule until August 11th or 12th, but in one or two cases terminated on July 31st, and at one or two places continued until August 13th. In one case only the duration reached 29 days, while in a few instances only the minimum number of 15 days was recorded.

Comparative Summary of Droughts, 1887—1916.

NOTE.—The values previous to 1910 have been increased to the equivalent of 100 stations for ready comparison.

Two stations in the east of England recorded a second drought in May, and two in the west of Scotland noted a drought in March. There

were no absolute droughts in the greater part of Scotland or in the centre or north of Ireland.

Partial droughts were also less frequent than usual, only 44 being reported from 43 stations, and the duration also was less than the average. In England and Wales (except at two stations where a second partial drought occurred in January and February) and in Ireland, the one great partial drought included the absolute drought of July and August, commencing at various dates between July 2nd and 18th, and terminating at various dates between August 10th and 24th, but usually on the 12th. The greatest duration was 43 days. In Scotland a partial drought in February and March affected only a small area.

RAIN SPELLS IN 1916.

A RAIN SPELL is a period of *more than* 14 consecutive days every one of which is a rain day.

The number of rain spells recorded in 1916 at the 100 selected stations was 231, or 61 more than the average of the 14 years available for comparison. Of these years only one recorded a larger number, and that was 1903, with 282, the remarkable character of which first suggested the systematic study of rain spells. The mean duration of the rain spells of 1916 was 20 days, or 1 day less than the average, but the mean rainfall per day was .29 in., or .03 in. above the average, a figure which was equalled in 1911, 1913 and 1914, but never exceeded. The general frequency of long-continued rainy weather is indicated by the fact that only 19 stations out of the hundred failed to report a rain spell, and these were mainly in the eastern counties of England and Scotland. Three or more rain spells were reported from 40 stations, or 14 more than the average, the number having been exceeded only in 1903 and 1910. The stations where many rain spells occurred were, as usual, those in Ireland and the west of Great Britain.

Comparative Table of Rain Spells at 100 Stations.

Rain spells occurred somewhere in every month of the year except September, but of the 231 cases dealt with only 14 were in the five months between May and September inclusive, none of these being in England, while the five months, January to March, and October to November, accounted for 168. There were only 9 instances in December. Nearly

half the recorded rain spells were in two periods, the first extending from the latter part of December, 1915, into January, 1916, the second in October and November, 1916.

The great winter rain spell which brought in the new year was practically universal over Ireland and the south and west of Scotland, but affected only a small part of the west of England and Wales.

The great autumn rain spell of October and November scarcely affected Scotland or the north-east of England ; but it appeared in most parts of Ireland, Wales, and the west and south of England.

The minor rain spells were of a local character and for the most part occurred in the regions of the west and north, where rain is normally frequent and persistent.

We print as usual a table of the rain spells with an average daily fall of .40 in. or more. As usual the Lake District shows the most remarkable instances, all the five recorded at Dungeon Ghyll being repeated in the extreme list ; the daily average of each of these exceeded half an inch, and the most remarkable just fell short of an inch.

Table of Rain Spells, 1916.

DURATION OF RAINFALL IN 1916.

RECORDS are again available from 48 recording rain gauges. Four which appeared last year have dropped out, unfortunately including the only record from the Highlands. Four which did not appear last year are added, including the return of the record from University College, Cork, two new London records from the Meteorological Office, and the Greg Observatory, Lancaster.

The Camden Square record, so far as the annual totals are concerned, is compared with the 35 years' average in a special table. This shows that the duration in 1916 was greater than in any other year except 1903 since observations of duration began in 1881. This is in accordance with the rainfall, the amount of which in 1916 was second only to that in 1903. The mean rate of rainfall per hour was close to the average, and has frequently been exceeded. The months with greatest duration were February, March, and November, these three yielding practically half the duration of the year.

Mr. Salter's paper on the measurement of rainfall duration, an abstract of which is given in Part I. of this volume, lays stress on the problems of interpreting automatic rainfall records, and calls attention to the differences which may arise through the use of various patterns of recorders. Mechanical differences are well brought out in the four records at Mount St. John, Thirsk, where Mr. Walker found the duration of rainfall in 1916, as given by the four types of gauge, to be 688·6, 691·6, 639·9 and 631·4 hours respectively. We do not propose to enter on a discussion of instruments or methods on this occasion, and merely remark that the computations of the Meteorological Office—those records printed in old style type—take account only of rain falling at a greater rate than ·004 in. (or exactly 0·1 mm.) per hour, while the other records may include rains of less intensity.

Taking the figures as given in the following tables, the greatest duration for the year was at Eskdalemuir Observatory, with 1451·2 hours, Cray Reservoir, Breconshire, coming close after with 1396·3 hours, and five other stations also recorded more than 1000 hours. These were all in the west of England, South Wales or Yorkshire. The least duration was at Nottingham, with 461·8 hours, the only instance less than 500 hours in the year. Roughly speaking the duration was greatest in those parts of

the country near which the greatest rainfall occurs. There is no doubt that the year was everywhere characterized by longer rainfall than in 1915, which was itself remarkable in this respect. We are of opinion that only 1903 had a greater duration than 1916 so far as the records can show.

Comparison of Amount, Duration and Intensity of Rainfall, and Number of Rain Days at Camden Square in 1916 with the Average for 35 years, 1881-1915.

HEAVY RAINS IN SHORT PERIODS IN 1916.

THE list of intense rainfalls in short periods in 1916, which appears on pages [42-43] is the shortest which has appeared in any volume of *British Rainfall* since 1887. We fear that this may be due in some measure to the preoccupation of many Observers who are not able to devote so much attention to their rainfall records as in normal times, on account of the war, but there is little doubt that the year was characterized by an unusual infrequency of thunderstorms, to which most of the intense falls are due, and this fact is borne out by the section on Heavy Rains on Rainfall Days.

The instances quoted are all those which exceed the limits of intensity defined by the lowest of the three curves in the diagram on page [41]. These limits, and those of the two higher curves, are set out also in Table I. and full particulars of the methods by which they were arrived at were given in *British Rainfall, 1908*, page 73. In the general table a cross is attached to any entry which exceeds the lower limit of "remarkable" falls, and two crosses are attached in the case of "very rare" falls.

TABLE I.—*Limits of Exceptional Falls.*

Minutes.	WORTHY OF NOTICE.		REMARKABLE.		VERY RARE.	
	Amount.	Rate per hour.	Amount.	Rate per hour.	Amount.	Rate per hour.
10.....	.30	1.80	.65	3.90	1.00	6.00
20.....	.53	1.59	1.06	3.18	1.58	4.74
30.....	.70	1.40	1.35	2.70	2.00	4.00
40....	.82	1.23	1.54	2.31	2.26	3.39
50.....	.92	1.10	1.67	2.00	2.42	2.90
60.....	1.00	1.00	1.75	1.75	2.50	2.50
70.....	1.07	.92	1.81	1.55	2.54	2.18
80.....	1.12	.84	1.85	1.39	2.57	1.93
90.....	1.15	.77	1.89	1.26	2.60	1.73
100.....	1.18	.71	1.92	1.15	2.62	1.57
110.....	1.21	.66	1.93	1.05	2.64	1.44
120.....	1.23	.61	1.94	.97	2.65	1.33

The "very rare" rainfalls form a class by themselves, and Table II. brings together all those which are known to have occurred in one hour

TABLE II.—*Rainfalls of very rare Intensity lasting for one hour or less.*

* Did not appear in *British Rainfall*.

or less in the British Isles since 1868, when the collection of such records was begun. Such rains have been recorded on the average about once

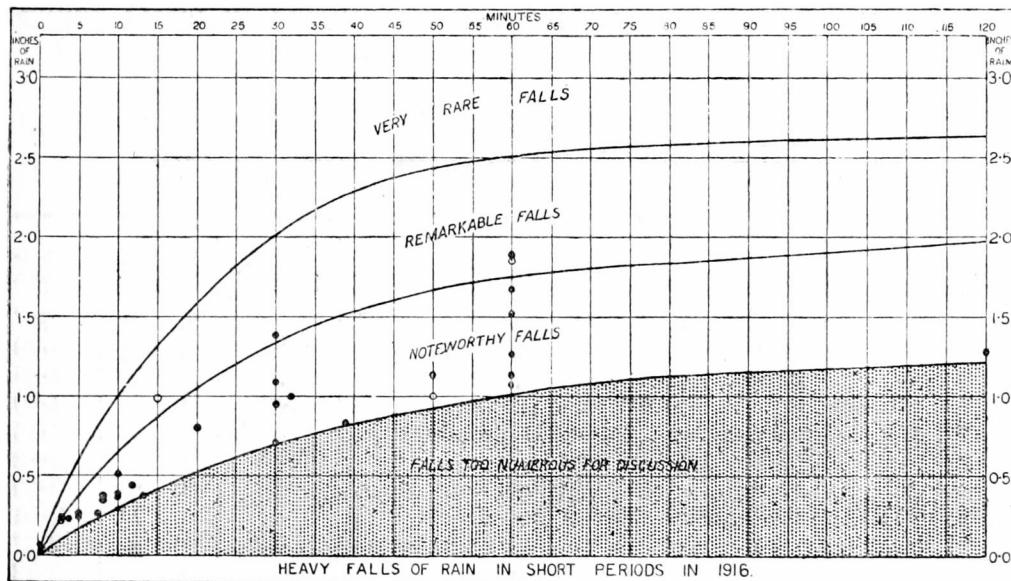

in each year, though as a matter of fact only 24 out of the 49 years find a place in the list. The list has not been added to in 1916.

A rough idea of the comparative frequency of intense rainfalls may be gathered from the comparison of the number of heavy falls of two hours' duration or less in 1916, with the average of similar data for the previous 48 years. In spite of the greatly increased number of Observers during recent years the 1916 records only just reached the average values. When allowance is made for the number of records available the year is found to have had as small a number as any during the preceding 30 years.

Number of Noteworthy Rains of two hours duration or less.

Average.	England and Wales.				Scotland.	Ireland.	Total.	Per cent. of records received.	
	S.E.	S.W.	N.E.	N.W.					
{ 1868-1915.)	15.5	7.4	4.2	2.0	29.1	2.2	1.1	32.4	1.0
1916.	14	5	6	4	29	1	2	32	0.6

The records for 1916 of falls of two hours or less are shown in the following diagram. Although none of these exceeded the lower limit of

When an entry in Table III. is queried, the dot representing the fall is hollow.

"very rare" falls, two intense rains of duration longer than those indicated in the diagram certainly merit the double cross. These were the falls of 3.51 in. in 2 hours 30 minutes at Goff's Oak, near Cheshunt, Hertfordshire, on August 17th, and 2.91 in. in 2 hours 10 minutes at Hacketstown, Co. Carlow, on July 24th. Full particulars of these storms

both of which exhibited the characteristic feature of being confined to remarkably small areas, will be found in *Symons's Meteorological Magazine*, Vol. 51, pp. 106 and 119. The four "remarkable" falls indicated on the diagram passed the lower limit only by a narrow margin. These were 1.88 in. in 1 hour at Wester Hall, Humshaugh, Northumberland, on June 24th, 1.85 in. in 1 hour at Great Moulton, Norfolk, on May 28th, 1.37 in. in 30 minutes at Rettendon Place, near Battles Bridge, on April 27th, and .24 in. in 3 minutes at Plymouth, on August 23rd. The Rettendon rainfall was remarkable for occurring unusually early in the year, intense falls being rare in England before May. In this connection we may mention a striking rainfall recorded by Mr. R. H. Curtis, at Warlingham, on November 7th, an extremely late date for intense rainfalls. Mr. Curtis measured 1.24 in. as the result of two heavy showers, lasting in the aggregate 15 minutes, but as we have no particulars of the individual showers, the record cannot legitimately find a place in Table III.

The remaining intense rainfalls of 1916, so far as reported to us, call for no special comment, and the records for the year may be regarded as taking a relatively unimportant place in the history of heavy rainfalls of short duration.

HEAVY FALLS ON RAINFALL DAYS IN 1916.

FOR the purpose of this discussion every record of daily rainfall which has been received has been examined, the total number of records being 4,402. In the great majority of cases the records show that the wettest day of the year had so small a rainfall that no special interest attaches to it. Experience has shown that a daily rainfall of 2·50 in. or more is sufficiently uncommon to be worthy of special record and accordingly every instance of such a maximum fall in 1916 has been extracted and appears in the following Chronicle. In some parts of the country, however, falls of this magnitude are so rare that many remarkable instances of very wet days would pass unnoticed if nothing smaller were to be recorded, hence we have also extracted from the daily records the rainfall of the wettest day in the year when that reached 7·5 per cent, of the total rainfall of the year, thus according to the total rainfall, maximum falls as low as 1·50 in. for a station with a fall for the year of 20·00 in. appear in the Chronicle. Thus no day the rainfall of which was exceptional for the locality has been omitted. In the case of wide-spread storms a short description compiled from Observers' notes, meteorological statistics and newspaper descriptions has been added, and the most interesting instances are illustrated by maps, in compiling which the records of perhaps 1,000 stations have been employed. In order to save space the number of these maps on the present occasion has been reduced to a minimum, but those which appear are the more interesting on that account.

With regard to falls of 2·50 in. or more on one day, in addition to the instances specified in the Chronicle, there were 84 cases at 46 stations of other falls greater than that amount, and one station, Kinlochleven, in the west of Scotland, had no less than 7 days in the year with more than 2·50 in. each, while Pen-y-Gwryd, in the north-west of Wales, had 6 such days.

Number of stations with two or more falls of 2·50 in. or more in 1916.

In *British Rainfall, 1910*, pp. 29-36, we published a list of the largest maximum daily falls recorded for each county in the British Isles, and when the maximum exceeded 4 inches, every instance of falls greater than 4 inches was given, except at a few Lake District stations, where the limit was taken at 5 inches. This list has been kept up to date by additions published from year to year, and 1916 has made changes necessary in eleven counties comprising the 25 entries which follow :—

Div.	County.	Station.	Date.	Rainfall.
V.	Wiltshire .. <i>substitute</i>	Donhead St. Mary ..	Aug. 29th, 1916..	4·38

XXII.	Mayo „ <i>substitute</i>	Aasleagh House	Nov. 16th, 1916..	3·47

The above additions include the largest daily rainfall hitherto recorded in the British Isles, the fall of 8·20 in., at Kinlochquoich, on 11th October, which displaces the former highest figure of 8·03 in., at Seathwaite.

Part I.—The Chronicle.

A remarkable feature of the year is that there were no widespread heavy rains in the first six months, and in that period only sixteen entries of sufficient magnitude to quote were recorded.

January 1st.

The heavy fall at Alston marks a local downpour in the north-west of England which produced a "new year's flood" in the neighbourhood of Carlisle.

X.	Alston (Nenthead)	2·62 in. or 3·2 per cent.

July 7th and 8th.

July 7th was perhaps the wettest day ever recorded for the east of Scotland. It was the wettest day of the year at more than 140 of the

RAINFALL. JULY 7TH, 1916.

Scottish stations and no less than 74 instances of falls exceeding 2·50 inches are quoted in the following list, the largest figure being 3·80 in., at Craig Mills, Murroes, Forfarshire.

The rain, which culminated on the 7th, commenced on the rainfall day of the 6th and continued so far as can be ascertained as an unbroken fall far into the 8th. It should thus be discussed as a whole and represented in a rainfall map showing the accumulated fall of the three days, and we much regret that the difficulties under which the present volume is being prepared have made it impossible to deal with the phenomenon thus fully. In the wettest region around Perth the continuous fall during the three days amounted to more than 5·50 in., and much damage to property was caused by the resulting floods. We reproduce on p. 47 a map of Scotland showing the distribution of rain on July 7th, from which it appears that the west of the Outer Hebrides and the southern half of the Inner Hebrides were rainless on that day. The west coast of Scotland south of Skye, the extreme north of Scotland, and the north-east of the counties of Banff and Aberdeen, had less than half an inch of rain. More than one inch fell from the Tweed to the Dornoch Firth in one direction, and from the east coast to the borders of Ayrshire and Argyll in another. More than 2 inches spread north from Selkirkshire in an area which gradually widened until it stopped in the north of Perthshire and Forfarshire. A similarly shaped area with more than 3 inches stretched from Edinburgh far into Perthshire and Forfarshire, and on the strength of a record which was incomplete and therefore could not appear in the table, a spot with just over 4 inches has been placed on the map near Perth.

The following is a summary of the areas measured on a large scale map with the corresponding volumes of precipitation where it exceeded 1 inch :

Rainfall of July, 7th, 1916.

	Area, sq. miles	General Rainfall, inches.	Volume of Rain, sq. miles x inches.
More than 4 inches	29	4·10	119
3—4 inches	818	3·33	2724
2—3 inches.....	3656	2·43	8872
1—2 inches.....	11226	1·50	16894
Total	15729		28609

This represents a general rainfall of 1·82 in. over the 15,729 square miles which had a rainfall greater than 1 inch on this day.

The relation of the portion of the country affected by this remarkable downpour to the movement of the meteorological disturbance producing it is of more than usual interest, and a special small scale map is given on p. [50] showing the track of the depression on the 7th and in a general way the distribution of rainfall over the British Isles. It will be observed that the rainless area of the Hebrides continued throughout Ireland except for two points on the coast, and that no rain fell in parts of the west of Wales and England or along the south coast. Rainfall exceeding one inch which is shaded on the sketch map was confined to Scotland and a tract along the Pennine range, all lying well to the left of the track of the depression. As the rain represented on this map was measured at 9 a.m. on the 8th, when the centre of the depression was probably off the Tweed, it is clear that for the most part it must have fallen in advance of the depression. The fact that no heavy rain fell in England to the right of the depression is worthy of note and important, as the track of a depression producing heavy rain on its left rarely leaves a sufficient land area on its right to allow the absence of heavy rain to be demonstrated in that quarter. A second sketch map shows the continuation of the track for part of the rainfall day of July 8th, and indicates the fact that more than an inch of rain fell on that day across Forfarshire and Perthshire, while there was no rain north of the middle of Ross-shire or in the greater part of the north of England. Although the rainfall on the 8th reached 2 inches at only one spot on the south of the Firth of Tay, the following table shows that the volume of rain falling on that day was by no means insignificant.

Rainfall of July 8th.

	Area, sq. miles	General Rainfall, inches.	Volume of Rain, sq. miles x inches.
More than 2 inches	11	2.09	23
1—2 inches.....	2383	1.27	3029
Total	2394		3052

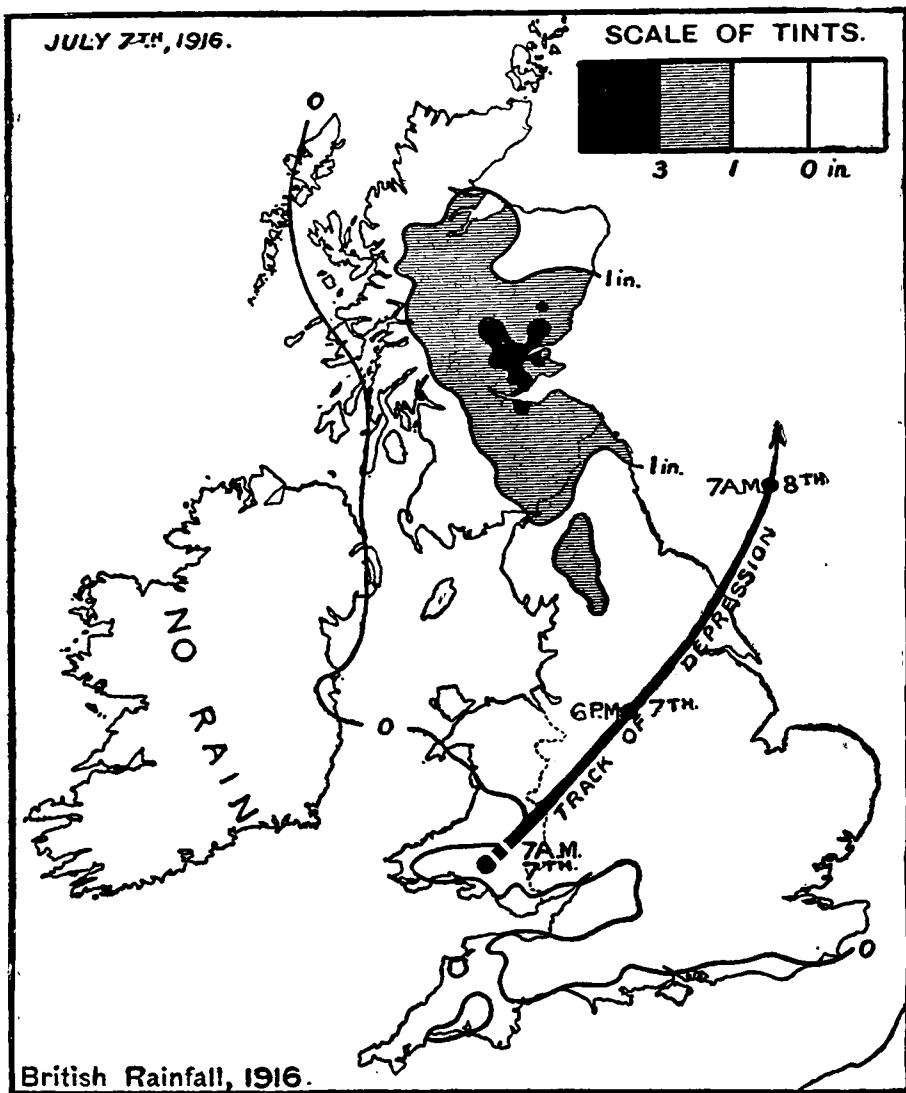

This shows a general rainfall of 1.27 in. for the areas on which more than 1 inch fell.

Mr. J. Fairgrieve, who plotted the original maps, has kindly made the following notes on the time at which the rain fell, mainly derived from the *Daily Weather Report* :—

“ During the rain day of the 6th the cyclone moved from somewhere south-west of Ireland to about Pembroke. At 7 a.m. rain was falling in the

south-west of Ireland, of Wales, and of England. At 6 p.m. there was an area of rain in front of the cyclone which covered the central area of the British Isles. At 7 a.m. on the 7th a belt about 100 miles wide, in which rain was falling, stretched from the north-west of Scotland to Sussex and

RAINFALL AND TRACK OF DEPRESSION, JULY 7TH, 1916.

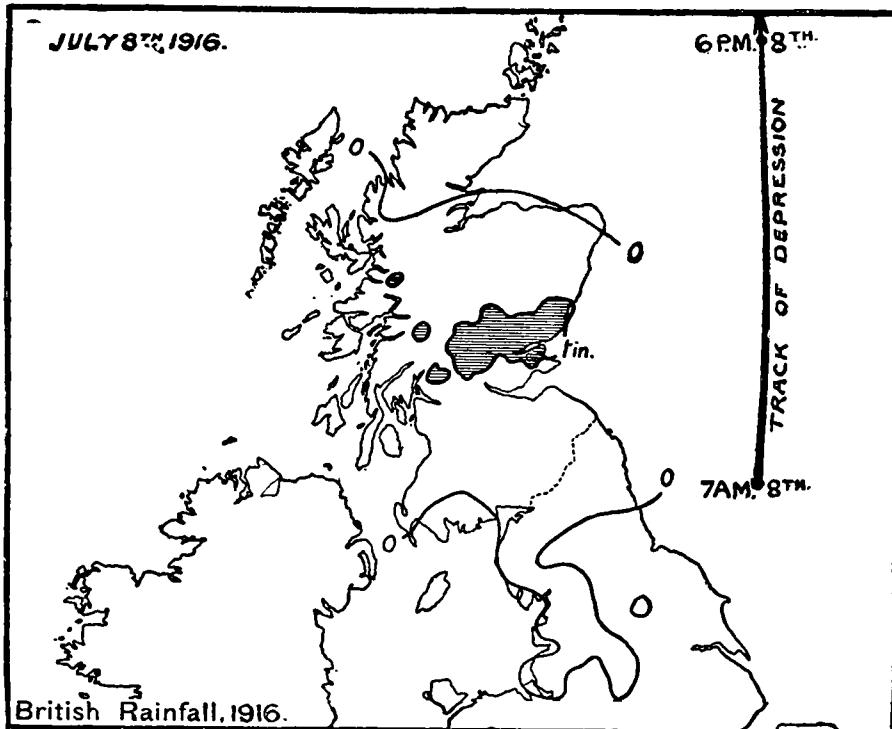

Kent, and thence south-west to Corunna. There was also rain on the north-west of the cyclone, from Donaghadee to Birr Castle (falling on the rainfall day of the 6th).

During the rain day of the 7th the centre of the cyclone moved from somewhere near Pembroke to somewhere off the coast of Northumberland.

As has been said the map for 7 a.m. shows a belt of rain along the axis of Great Britain. This belt probably moved eastward and was succeeded in the afternoon by thunderstorms in the south-eastern counties, south of the track of the cyclone. The map for 6 p.m. (on the 7th), shows rain to have

RAINFALL AND TRACK OF DEPRESSION, JULY 8TH, 1916.

withdrawn northwards and to be only to the north or north-west of the cyclone on an area practically confined to Scotland but stretching along the west of England to about Liverpool. The map for 7 a.m. on the 8th again shows rain only to the north of the cyclone, and again it has moved further north, leaving southern Scotland dry. The rain over the south and south-east of England is probably partly due to the belt of rain in front of the cyclone in the forenoon of the 7th, but in greater part to thunderstorm rain in the afternoon.

Conclusion.—It seems fairly evident that the heavy falls in Scotland on the rain days of the 7th and 8th are related in some way to the passage of warm and damp southerly, south-easterly or even (in the later stages) easterly winds over cold easterly, north-easterly or northerly winds, while the rain in England is related to the passage of westerly winds under southerly winds in front of the storm and to thunderstorms following."

July 24th.

A violent but very local thunderstorm in Ireland.*

XXI.	Hacketstown Rectory	3·01 in. or 6·4 per cent.
------	---------------------------	---------------------------

July 26th.

A violent rainstorm over a very small area, of the type to which the name of cloud-burst is frequently applied, occurred near the little lake known as Llyn-y-Fan fach in Carmarthenshire. We cannot quote definite figures as they have not been supplied by the Rural District authorities who are responsible for the rain gauges, but the rainfall as measured did not appreciably exceed 2·50 in. The interest of the occurrence lies in the fact that it took place while works were being carried on to obtain a water supply, under the direction of Mr. H. J. Rose, C.E., who has supplied the following description from notes made by Mr. D. A. Howell, the resident engineer.

" The tarn in question, about one quarter of a mile long, lies at the northern base of a great precipice of old red sandstone cliffs, which also surround a somewhat larger tarn two miles to the east. A stream called the Sawdde flows from the tarn and on it half a mile down the valley the intake works are situated, just below the confluence of a little stream, the Sychlwch, which flows from the screes at the base of the great cliff between the two tarns. The rain gauges are situated on the Sawdde, one just above,

* See *Meteorological Magazine*, August, 1916. Vol. 51, p. 106.

the other half a mile below, the junction of the Sychlwch. Rain began to fall gently about 1 p.m. and became very heavy about 2 p.m., when a terrific thunderstorm broke. The flow of the stream from the lake, and that of another stream, which flowed into it about a mile further down was not greatly increased, but a tremendous flood came down the Sychlwch raising the level of the main stream 4 feet in fifteen minutes when the mechanism for registering the water level ceased to act. The whole of the intake works were soon covered by the flood and thousands of tons of boulders and debris were brought down. At 2.45 the storm was over. The centre of the storm was probably on the summit of the cliff between the two tarns and the rainfall there must have been greatly in excess of the 2.50 in, measured by the gauges on the margin of the storm area. On the slopes and summit of the cliffs huge masses of red sandstone and peat had been torn out to a depth of several feet, the latter revealing the clay and red sandstone underneath. The flood water which entered the valley from the storm centre caused great destruction for a long distance, cutting a new channel for the stream to a depth of ten feet in some places, excavating the recently laid pipe line and piling mounds of boulders and sand to a height of ten feet or more on some parts of the valley floor. At the height of the storm the crashing of the huge boulders down the valley and the lashing of the rain created an uproar which completely drowned the noise of the thunder."

August 29th.*

The heavy rainfall of August 27th in the west of England was followed on the 29th by an even more prolonged and widespread rain which affected the whole south of England from Devonshire to Norfolk, and yielded maximum falls of sufficient magnitude to be quoted in the following table at 117 stations, including 45 at which the rainfall for the day was more than 3 inches, and two at which it was more than 4 inches. In the western counties the day was the wettest since August 28th, 1910. The distribution of the rain was remarkable for its extreme patchiness, a feature which is well brought out in the accompanying map. It will be observed that the general distribution of the rain belonged to the familiar type associated with a depression moving up the Channel and producing surface winds from N.E. and N. over the greater part of the south of England. In this case the northern limit of precipitation was very sharply defined, no rain having fallen north of a line drawn from Pembroke to Flamborough Head. Except for one or two points on the south coast and in the west of Cornwall the rainfall for the day exceeded half an inch everywhere south of a line extending from the middle of Cornwall through Glamorgan to the coast of Lincolnshire, and the northern limit of falls exceeding 1 inch ran about 25 miles south of this line. The area with more than 1 inch extended along the coast, from Plymouth to Southampton, and then in a very irregular form the 1 inch isohyetal zig-zagged northward and eastward to the estuary of the Thames. An unusual feature in this distribution of rainfall was the presence of a group of areas with less than 1 inch ranged in order along the eastern half of the axis of the wet belt. The four largest of these comparatively dry areas

* See *Meteorological Magazine*, September, 1916, Vol. 51, pp. 120-121.

were situated respectively in Berkshire, Buckinghamshire, Bedfordshire and Norfolk. The western portion of the wet area contained three large tracts with more than 2 inches, including several spots where the fall exceeded 3 inches, while the eastern portion exhibited a double chain

RAINFALL, AUGUST 29TH, 1916.

of smaller 2-inch areas, one running from the Severn to the Wash north of the comparatively dry belt just referred to, the other south of the dry belt, from Marlborough to the coast of Suffolk, developing a 3-inch area in the last named county.

The measurement of the areas on the map yield the following figures :—

	Area, sq. miles.	General Rainfall, inches.	Volume of Rain, sq. miles x inches
More than 3 inches	622	3.23	2012
2—3 inches	4170	2.32	9690
1—2 „	18533	1.44	26750
.5—1 inch	11355	.77	8788
0-.5 „	10634	.26	2775
Total	45314		50015

This gives a general rainfall of 1·65 in. for the 23,325 square miles with more than 1 inch, and a general rainfall of 1·10 in. for the 50,015 square miles on which any rain fell.

The rain fell for the most part with northerly and north-easterly winds on the evening of the 29th and during the night of the 29th-30th.

-----	---------------------------------	---------------------------

October 11th.

The unprecedented storm in the east of Scotland on July 7th and 8th met with its counterpart on this occasion in the west Highlands, but as befits the high average rainfall of the west the falls were much greater and in the centre of the storm area the highest rainfall ever recorded in one day for the British Isles was experienced. At Kinlochquoich, in Glenquoich, the fall, as recorded by Colonel Cameron of Lochiel, for October 11th, amounted to **8.20** in. This glen has long been known as one of the wettest parts of Scotland, and it is fortunate in possessing three rainfall stations, at two of which daily observations are made. Kinlochquoich, at an elevation of 560 feet above sea level, has an annual rainfall considerably lower than that at Loan, 650 feet, but unfortunately the rain gauge at the latter station is only read monthly, and we cannot tell what it received on this day. Glenquoich Lodge, four miles east of Kinlochquoich, and practically at the same level, has normally a slightly lower annual fall, and on this occasion registered 5.82 in. for the day, a figure which confirms the larger value at Kinlochquoich. The greatest daily rainfall previously reported was 8.03 in., at Seathwaite in Borrowdale, on 12th November, 1897, this being the only other instance in which so much as 8 inches fell on a rainfall day in Great Britain or Ireland, although in the great Norfolk rain of August 26th—27th, 1912, 8.09 in. fell in 24 hours which formed part of two rainfall days, at Brundall. Unfortunately rainfall stations in most parts of the West Highlands are few and far between, and the map which illustrates this fall is much less certain as regards the run of the isohyetals than that for the July fall in the east of Scotland. The main lines of the distribution are, however, quite simple and definite, and a glance shows that they reproduce the general distribution of rain in a normal winter month, closely resembling the distribution of the annual rainfall in a normal year. The rain fell with a strong and steady S.S.W. wind due to a distribution of pressure dominated by a depression near Iceland and an anti-cyclone over the Bay of Biscay and

France. This was, in fact, an exaggeration of the normal prevailing wind of the region, hence the distribution of rainfall was dictated by the configuration of the land, being thus in direct contrast to the cyclonic rain of

RAINFALL, OCTOBER 11TH, 1916.

July 7th which brought the heaviest precipitation on what is normally almost the driest part of the country. The map shows that on October 11th rain fell in all parts of Scotland though there was less than

half an inch in the eastern and southern tiers of counties. More than 1 inch prevailed from the north of Renfrewshire through the west of Stirling, Perth, Inverness, Ross and Cromarty and Sutherland and throughout Argyll, and the area with more than 2 inches lay from ten to fifteen miles inside. More than 3 inches occurred from the north of Argyllshire to the middle of Ross over a distance of nearly one hundred miles, with an average breadth of about twenty miles; within this a patch with slightly more than 4 inches lay near Fort William on the south side of the great Glen, and a long narrow strip ran for nearly fifty miles through the west of Inverness-shire, with a core perhaps thirty miles in length, where the rainfall exceeded 6 inches, rising in the south of the area to the 8-inch maximum in Glenquoich. It did not seem necessary to estimate the volume of rainfall on this day as the small number of stations available for plotting the map makes it impossible to be sure that the heavy falls were continuous and not broken up into patches covering a smaller area than is shown. It is impossible that so huge a volume of rain could descend upon the land in one day without causing extensive damage, and we are not surprised to find that the West Highland Railway, with its branches to Fort Augustus and Mallaig, was rendered impassable for several days by numerous wash-outs which completely isolated Fort William. Many of the roads were destroyed by the deep ruts cut by the rain, and the hundreds of tons of débris carried down to the lower levels. Glen Nevis for a time was converted into a lake, and many sheep were lost. It is instructive to note that the damage recorded was chiefly from the region where the rainfall did not exceed 4 inches, but this is accounted for by the fact that the full fury of the storm was spent upon the wild mountains and glens beyond the railways and human habitations.

October 21st.*

The rainfall of this day was remarkable in bringing the highest fall ever recorded in the west of Ireland to the neighbourhood of Killarney, where 5.35 in. was recorded at the District Asylum, and 5.02 in. at Flesk Mills. Falls of 5 inches and over have only twice before been recorded in any part of Ireland, on each occasion at the very exceptional station of Glen-na-Smoel, Co. Wicklow. Considering the high falls at Killarney it is remarkable that only about a dozen stations in Ireland registered notable maximum falls on this day, but that is partly accounted for by a more widespread rain which occurred on November 16th in the same district with maxima generally higher, though not yielding such extreme individual falls as those of October 21st. A map is given of the latter fall showing that the rain did not extend to the north-eastern counties of Ireland or to the east coast, but that half an inch or more was confined to Cork, Kerry and the west of Limerick, Clare, Galway and Mayo. Only a small area in Cork and Kerry had more than 2 inches, and the intense fall was localized close to Killarney. The rainfall appears to have been due to the formation of a very small shallow depression near the mouth of the Kenmare River at 6 p.m. on the 21st, which travelled southward, deepening as it went and turned towards the east at 7 a.m. on the 22nd.

Part II.—Abstract.

The general conclusions to be drawn from the foregoing study of heavy falls on rainfall days are embodied in the four tables which follow. They are on the same plan as last year. Table I. gives the twenty largest maximum falls for the year, and is dominated by the great figure of 8.20 in. at Kinlochquoich, while no less than seven falls exceed 5 inches. Only three of the falls quoted occurred in the summer half year, one on May 31st, at Seathwaite, and two on August 29th at Donhead St. Mary and Torquay. Fourteen of the great falls took place in October, one in November and only two in December. With one exception all of these falls occurred at stations where the rainfall for the year exceeded 50 inches.

Table II. gives the twenty largest percentages of the annual rainfall which fell on one day and calls attention to the remarkable falls in the drier parts of the country, all being reported from stations which had less than 42 inches for the year. All these falls occurred in summer storms in July or August, and seventeen of them took place on August 29th. The highest percentage was 13.4, and only three cases are recorded in which the percentage exceeded 11.

Table III. gives the highest daily rainfall and the highest percentage for the period 1865-1869 and for each year since 1870, the Kinlochquoich figure being the highest in the list, displacing 8.03 in. at Seathwaite in 1897.

Table IV., which was introduced for the first time last year, deals with all the falls of rain beyond a certain magnitude, whether these were the greatest in the year or not, and for the purpose of comparison the figures for 1915 are reproduced.

It will be observed that the total number of records utilized is nearly 150 less than last year. The number of falls of rain in one day amounting to 7·5 per cent. of the annual total was much smaller than in the previous year in all places except Ireland, but as could be gathered from the Chronicle the daily falls of 3 inches or more are much more numerous. Falls of 2 inches or more were less numerous for England and Wales, though much more numerous for Scotland and Ireland than in the previous year. Readers may be reminded that the columns headed "per cent. of total" refer to the total number of stations yielding daily records, not to the total number of days with rain.

MONTHLY RAINFALL IN 1916.

As in former years the monthly rainfall in inches at 299 stations is set out in the long table at the end of this article. These stations are selected so as to be as nearly equidistant as possible and thus the mean rainfall for all the stations given at the end of each of the large divisions of the country gives a close approximation to the general fall of rain in each month. As a comparatively small number of stations have records long enough to yield a trustworthy average the table of the relation of monthly rainfall to the average has to be restricted to 107 stations, these also being selected so as to be as representative and as nearly equidistant as possible so that their means give a fair idea of the relation of the general rainfall to the average. The maps of monthly rainfall in inches, and as a percentage of the average, are not to be viewed as illustrations in the text ; they are the original documents on which the text is based.

The percentage maps were plotted on a scale of 60 miles to the inch from the 107 stations quoted in Table II. with a few others, and the lines are guided to some extent by reference to the maps of total rainfall.

The maps of total rainfall on the left hand page, though suffering from their greater reduction, are of a higher order of accuracy than the percentage maps ; they were plotted on a very detailed map on the scale of 20 miles to an inch from the records of about 2,000 stations, and reduced by hand to a scale of 60 miles to an inch for further photographic reduction.

Viewing the **British Isles** as a whole we find that three months, March, June and December, had practically the average rainfall, three months, February, May and October, were very wet, the last named month not having been equalled in rainfall since 1903, and three months, July, August and September, were decidedly dry, September remarkably so. It is interesting to notice that February was very wet and September very dry in 1915 also, though the extremes on that occasion were more marked than the present. An interesting parallelism may be seen on this occasion between the rainfall of October and November, especially as regards the great area with more than 10 inches of rain on the high ground of the west both of Great Britain and Ireland. Special attention may be called to the remarkable features of the rainfall distribu-

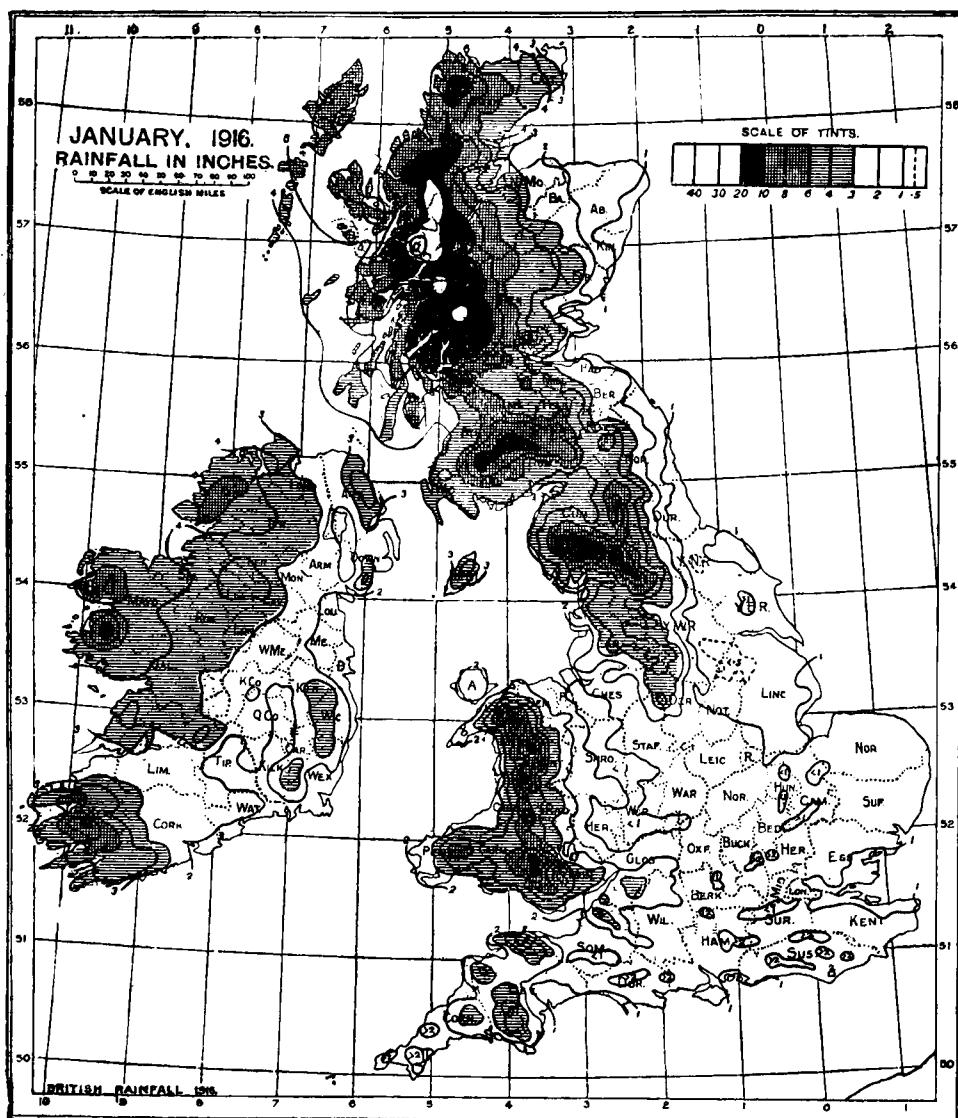

tion in two of the months. In March the effect of long continued steady easterly wind produced a map which fairly represents the average rainfall of the British Isles as it would be distributed if the wind blew as frequently from easterly quarters as it actually does from westerly quarters. In July the percentage map shows a quite exceptional simplicity indicating how the excess of rainfall round a very wet patch in the east of Scotland diminished in all directions and led up to a great deficiency round the periphery of the British Isles.

In **England**, as a whole, February was by far the wettest month, with practically twice the average fall, while March came next in wetness, giving the effect of an excessively inclement spring, an effect intensified by the fact that a very large part of the precipitation was in the form of snow. May, August, October and November were also wet, but June and December were nearly average, and July and September were very dry, while January and April were also dry months.

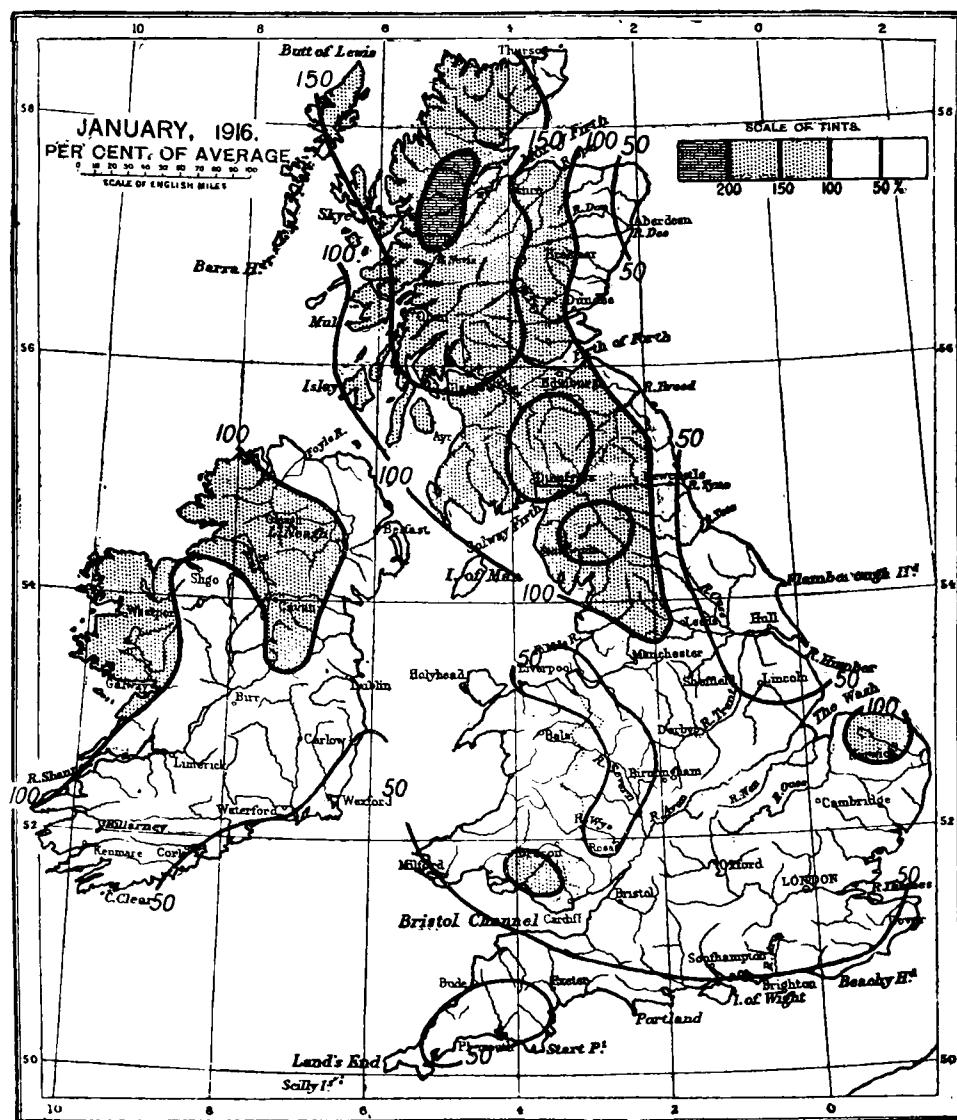

In **Wales**, as in England, the wettest month was February and the driest July. May and October were very wet months, April and June were close to the average, while January, March, August, September November and December, were dry, Wales being, on the whole, the driest part of the British Isles, with respect to its average throughout the year, having only had four months with more than the average fall as compared with eight months in England.

Scotland, which was the wettest of the great divisions on the balance of the year, had its wettest month in October, but January, May and February came little behind, while April and November were very wet, and June and July were wet also. December was close to the average in rainfall and three months only had less than the average, viz., March, August and September; September, with 56 per cent. of the average, being the driest month experienced in any part of the British Isles.

In **Ireland**, October was one of the wettest months on record, more than twice the average rainfall having fallen, while February, April, May and November were also very wet months. These wet months were, however, nearly balanced by seven very dry months. January, March and December, all fairly dry, were separated by wet months, but June, July, August and September made a solid block, with rainfall below the average, indeed, from June to September only three quarters of the normal rainfall fell.

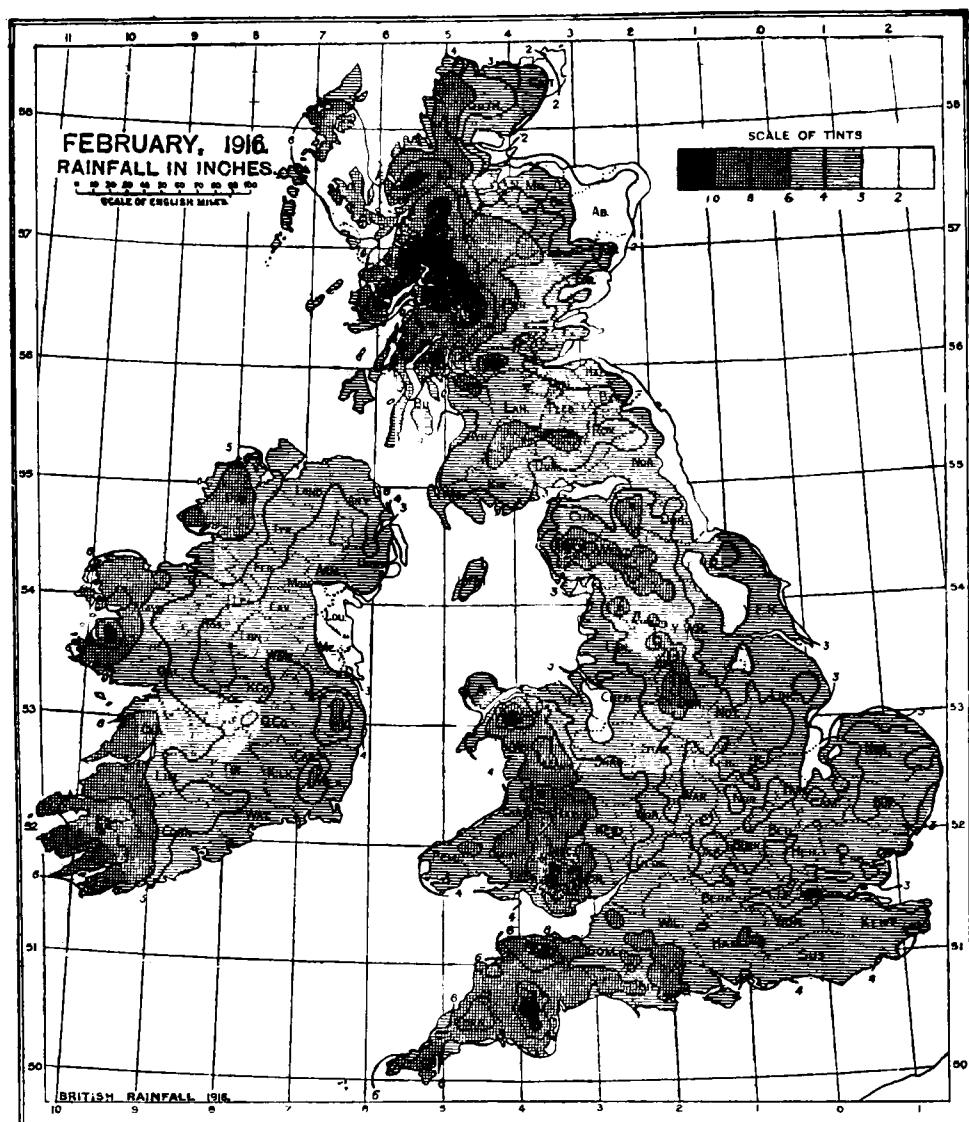

January—The most remarkable feature was the extremely high temperature which prevailed in association with high pressure in the south of England, and a series of depressions passing to the north of Scotland. The result was prevailing south-westerly winds leading to a rainfall which diminished from west to east but was abnormally light in the south and east, and abnormally heavy in the north-west. A few areas along the east coast had less than 1 inch of rain. More than 3 inches of rain only occurred on the high land in the west and over about half of Ireland. In Wales, the Lake District, the west of Ireland, and the south of Scotland small areas had more than 10 inches, but the area with more than 10 inches in Scotland was very extensive, and included a large

stretch where more than 20 inches fell, rising at one point to more than 40.

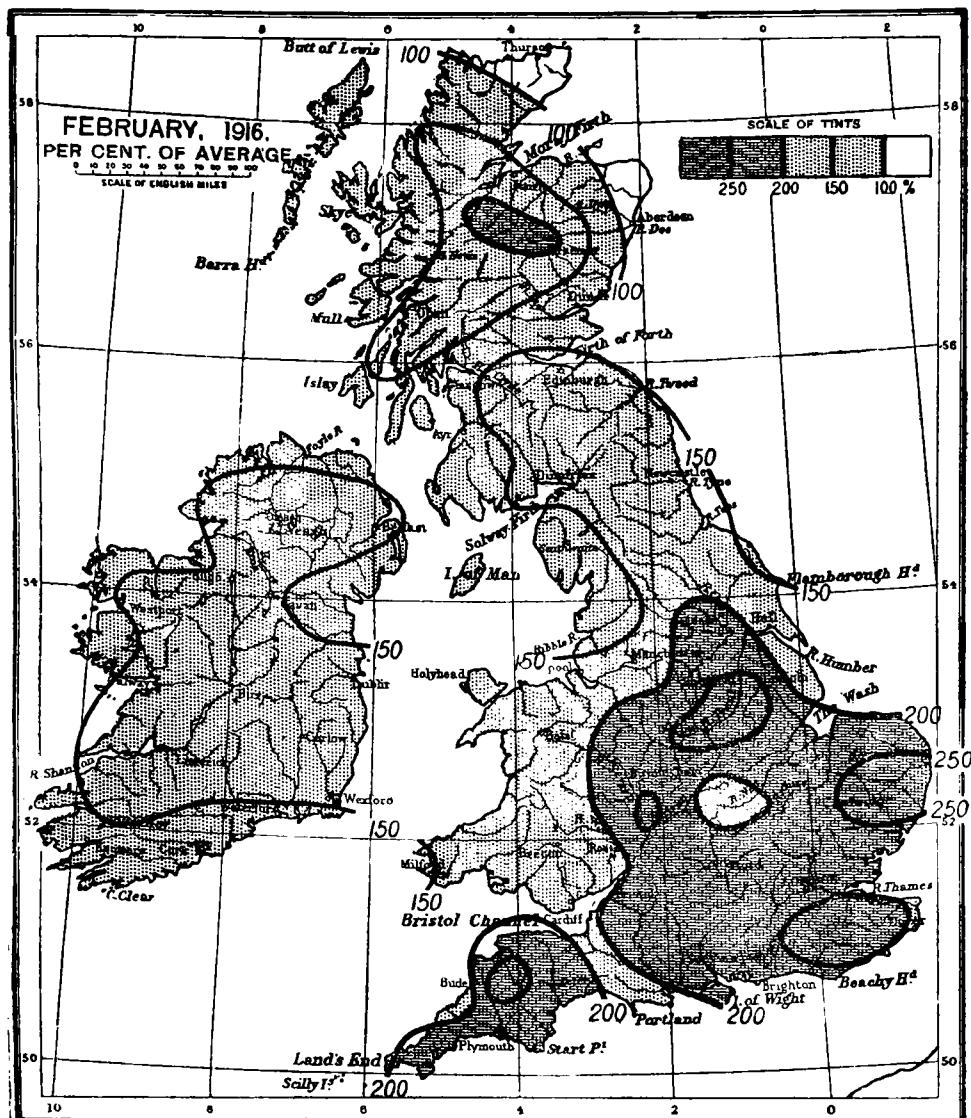

Both in Great Britain and Ireland the rainfall exceeded the average mainly in the north and west, a large part of Scotland had an excess of more than 50 per cent., and north of Fort William more than twice the average fall was experienced. Less than half the average fell in the east of Aberdeenshire, in the north-east of England, at a few points on the south coasts of England and Ireland, and on the eastern border of Wales.

The general rainfall of England was 15 per cent. below the average, of Wales, 23 per cent., and of Ireland, 13 per cent. below, while for Scotland it was 53 per cent above the average, and for the British Isles as a whole, there was an excess of 7 per cent.

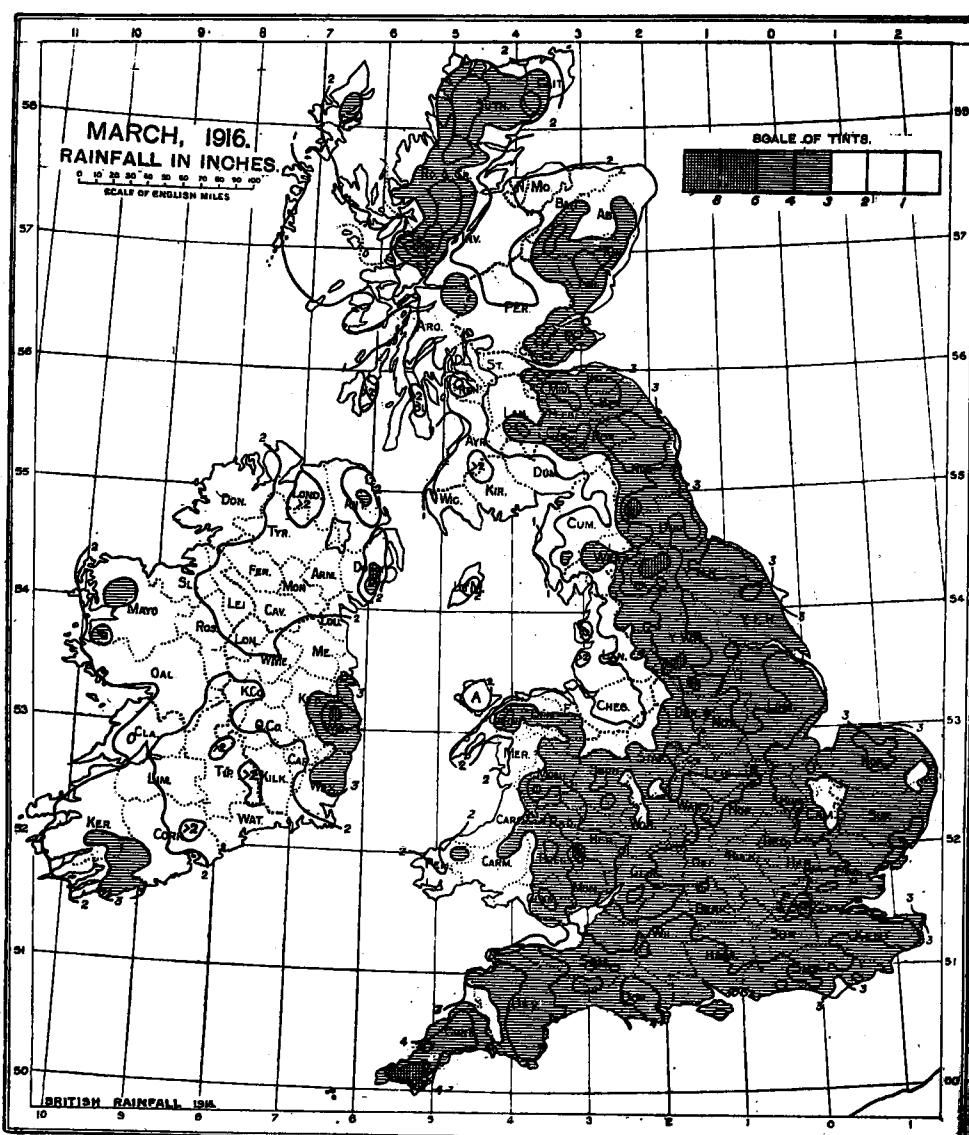

February had the highest rainfall of all the months in England and Wales, and was very wet in all parts of the country. This resulted less from very severe rain storms than from extremely frequent precipitation, mainly in the form of snow, which lay deeply over most parts of the country throughout the latter half of the month. Only a few small strips on the coast had less than 3 inches of rain, and only in the extreme north-east of Scotland did the rainfall fail to exceed 2 inches. A large part of the west had more than 6 inches, and patches with more than 10 inches appear on all the high western uplands from Dartmoor to Ross-shire.

Less than the average rainfall was confined to a narrow strip in the north-east of Scotland, no other month showing so small an area below

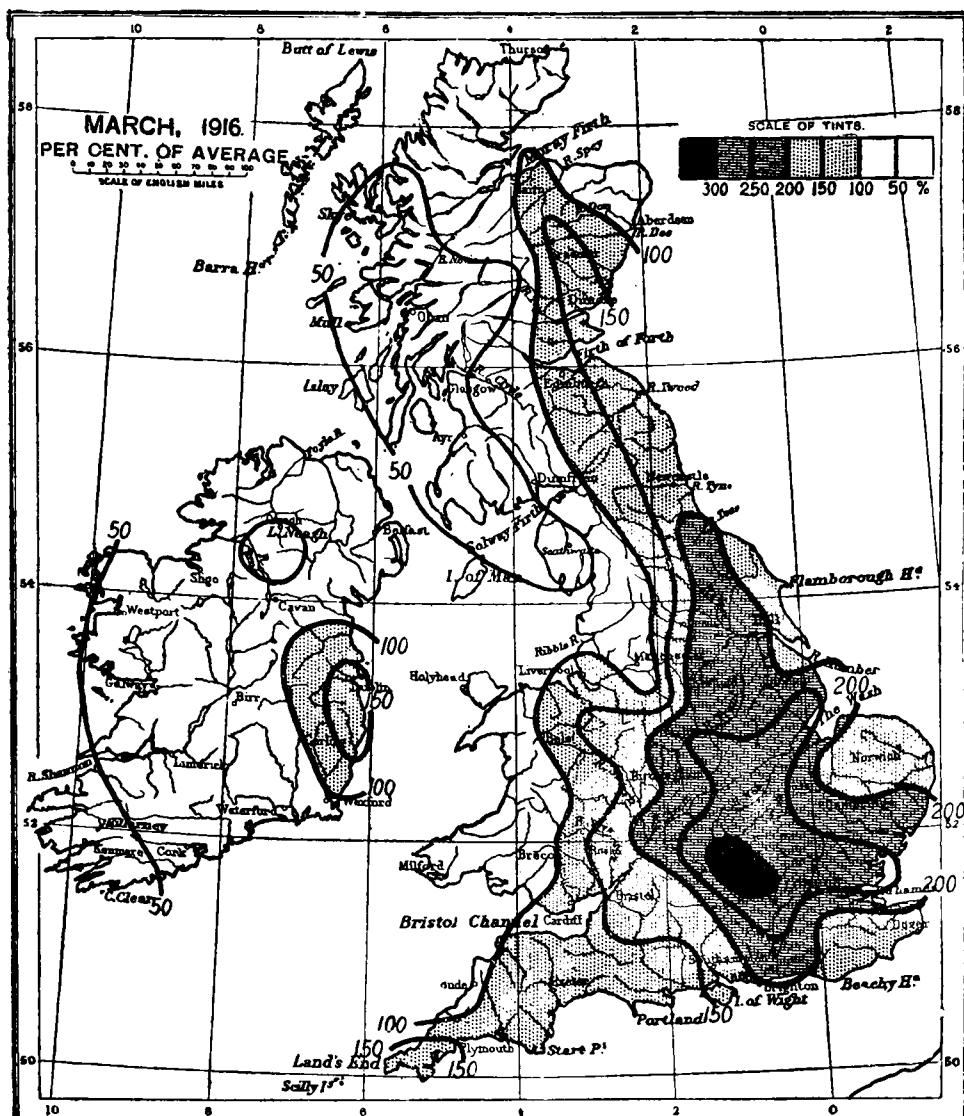

the average, or so slight a deficiency. On the other hand an enormous area in the south and east of England, and a small area in Scotland, received more than twice the average fall. It must, of course, be remembered that February is not only the shortest month but over a large part of England it is a month of minimum average rainfall, so that the total precipitation was by no means so great as an equal departure from the average would mean in other months.

The general rainfall for England was 99 per cent. in excess of the average. For Wales the excess was 74, for Scotland 48 per cent., and for Ireland 55 per cent. The excess for the British Isles, as a whole, was 69 per cent., a figure which was not surpassed in any other month.

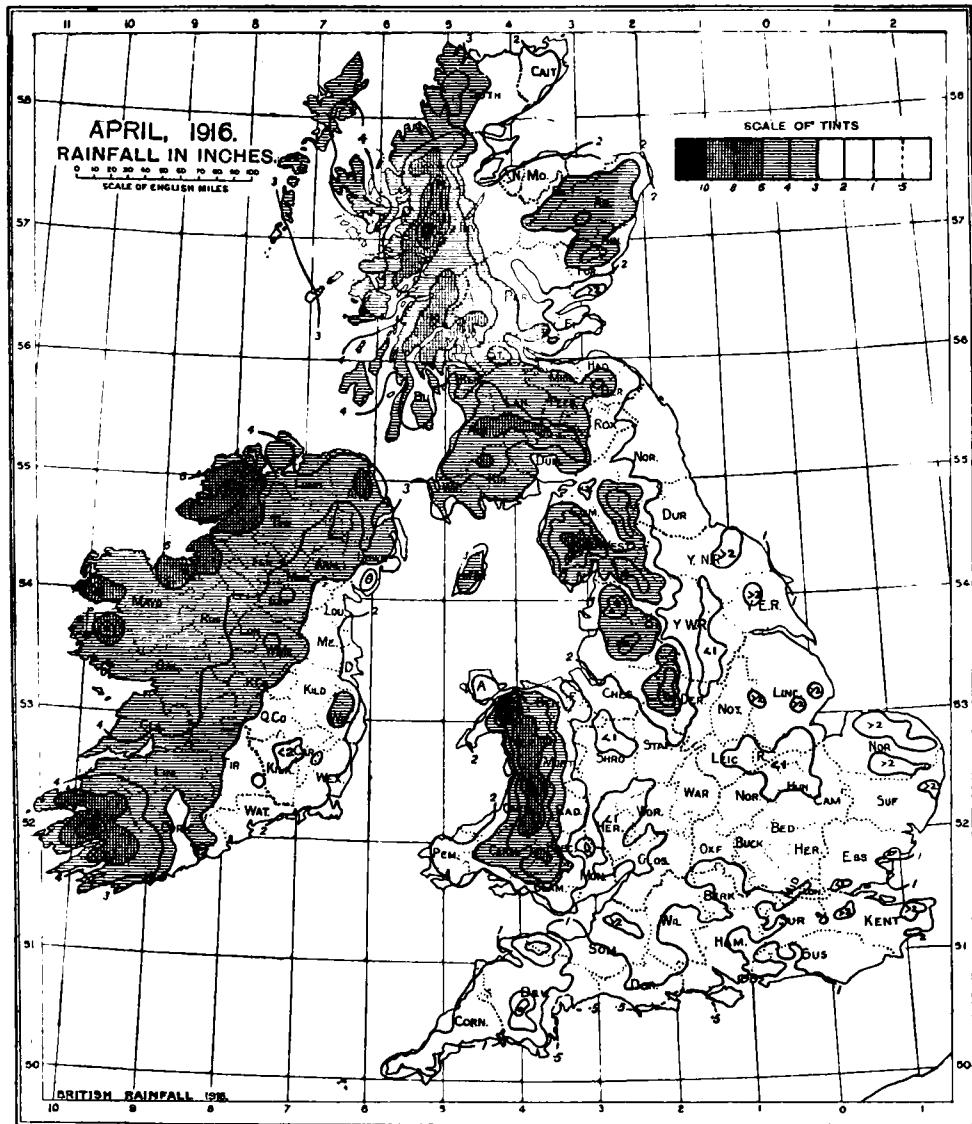

March exhibited an intensification of the common spring distribution of pressure, high in the north and low in the south of Europe, with the result that easterly and north-easterly winds prevailed throughout the month. The normal distribution of rainfall was completely inverted. Except in Scotland, north of the Firth of Tay practically no part of the east coast had less than 3 inches of rain, and a broad belt right up the centre of England had more than 4 inches. In the west of Scotland considerable areas had less than 2 inches of rain and some localities less than 1 inch, and such rain as fell towards the west coast obviously came with easterly winds. About half of Ireland had less than 2 inches of rain and only small patches more than 3 inches.

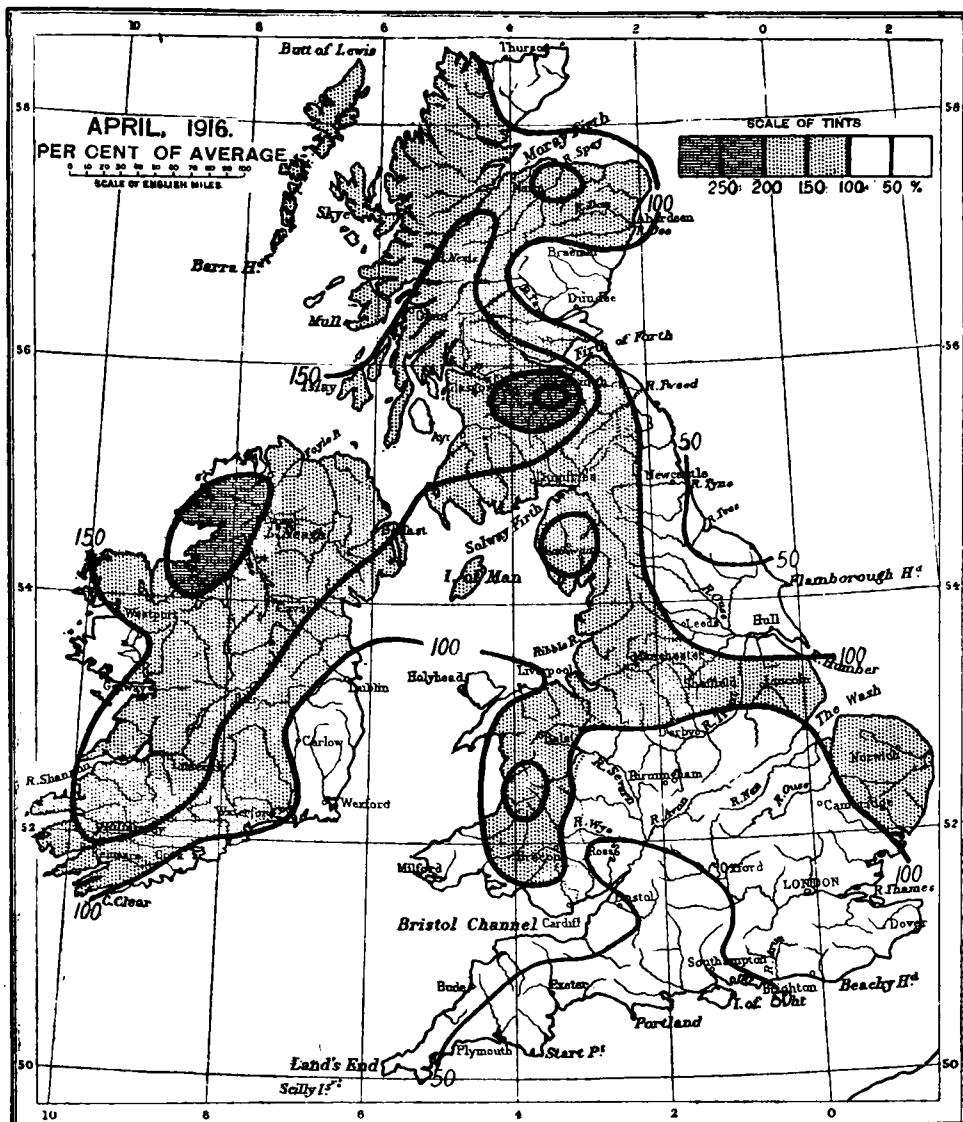

The west of Scotland, from Skye to the Solway, had less than half the average rainfall and this drought extended to the English Lake District. Part of the east of Scotland had an excess of more than 50 per cent., and a very large area of the east and centre of England had an excess of 100 per cent., while in Oxford and Bucks the excess was greater than 200 per cent. Almost the whole of Wales and Ireland were below the average.

In Scotland, with a general deficiency of 30 per cent., this month was the driest, except September. Ireland had a deficiency of 27 per cent., and Wales of 6 per cent., but England showed an excess of 58 per cent., the month being the wettest, except February. The British Isles, as a whole, had very nearly the average, there being an excess of 2 per cent.

April, for the most part, presented its typical changeableness of weather, and the rainfall, which was deficient in the south and east and excessive in the north and west, was distributed nearly in the normal fashion with more than 6 inches on much of the high ground in the west and less than 2 inches on the low ground in the east and centre; in fact, to the east and south of a line drawn from Dartmouth to Scarborough, more than 2 inches only fell on a few small patches, and much of the country had less than an inch. Less than 2 inches also fell around the Firth of Tay and the Moray Firth in Scotland, and along the east coast of Ireland.

The east of England, north of Lincoln, had less than the average

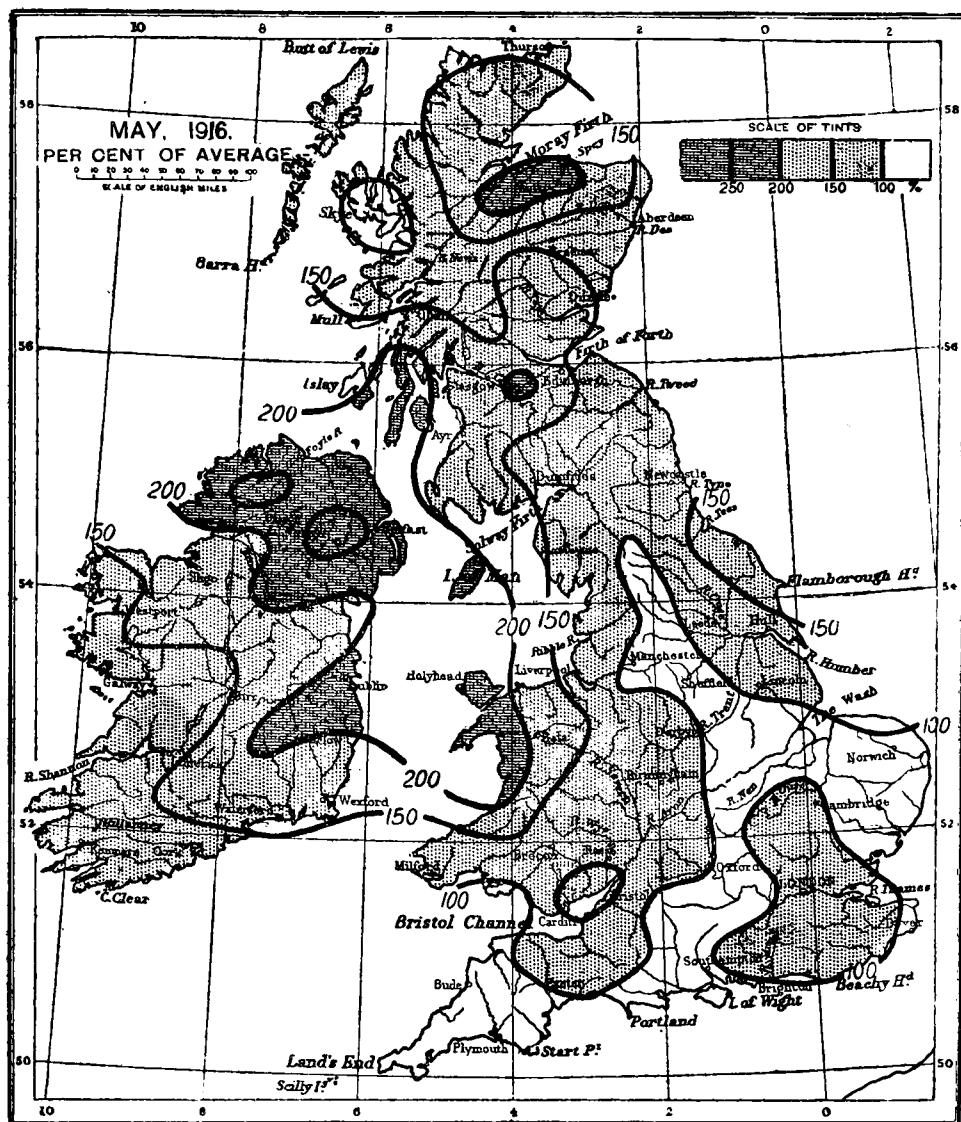

rainfall, and so had the Midlands and the South, south of Nottingham. A large tract, from the south of Cornwall to the Isle of Wight and northward to Gloucester, had less than half the average fall. An excess greater than 50 per cent. prevailed over the west and north of Ireland and the south-west and centre of Scotland, culminating in two tracts with more than twice the average rainfall in Sligo and Donegal in the one case, and to the south of the Firth of Forth in the other.

The general rainfall of England showed a deficiency of 17 per cent., Wales was nearly normal, with an excess of 2 per cent., but Scotland had an excess of 38 per cent., and Ireland of 51 per cent., resulting in an excess for the whole of the British Isles of 17 per cent.

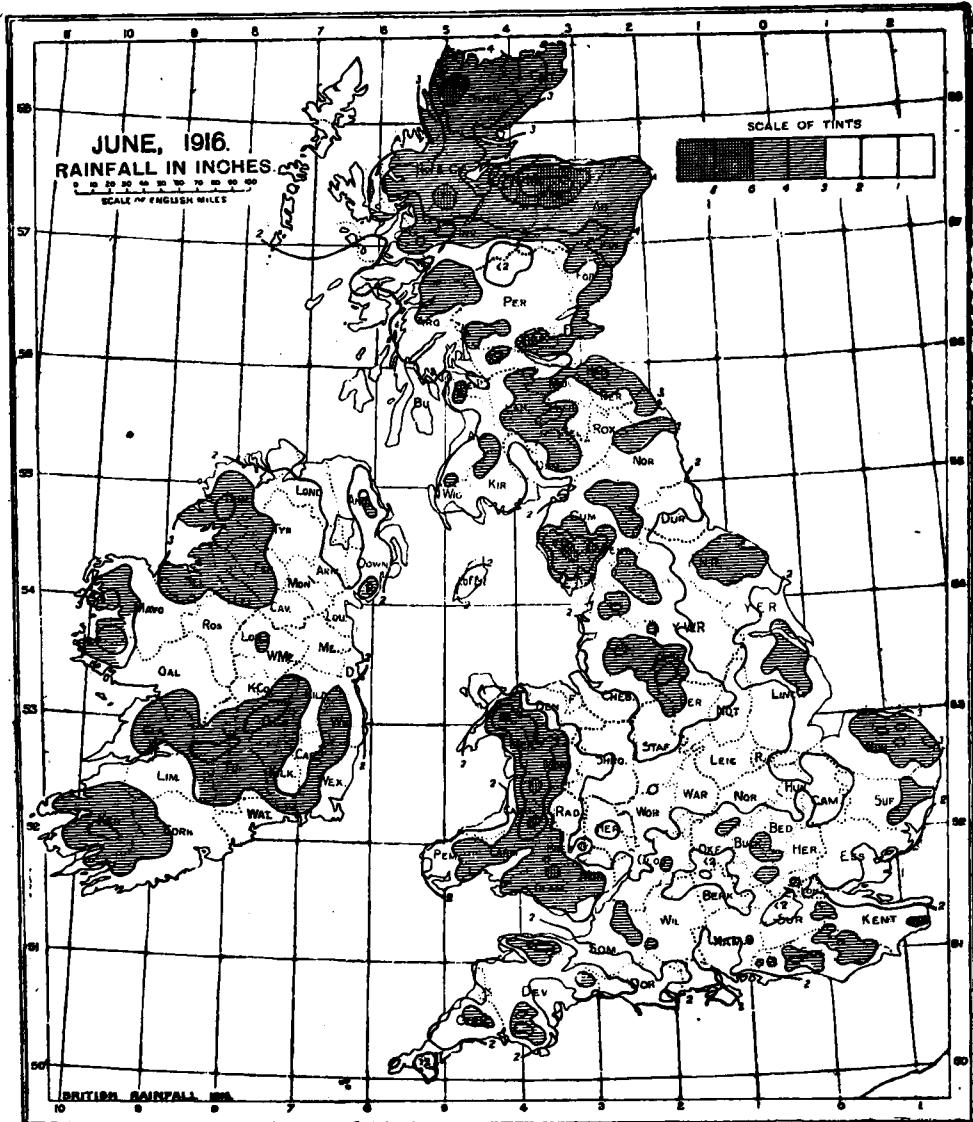

May had rather more than its normal share of easterly wind, but most of its rainfall was associated with the passage of cyclonic depressions, which led to many falls in the north of Ireland and west of Scotland, or to thunderstorms, which yielded a light but extraordinarily patchy fall throughout England. More than 4 inches fell in the centre of Wales and on an apparently continuous belt from the middle of Ireland to the north of Scotland, within which a number of areas had more than 6 inches, and in Mayo, Donegal and West Inverness, more than 8 inches. Falls of 10 inches were reported from three isolated stations. In England the rainfall reached 3 inches over a fairly wide area in the north and in a series of diminishing patches southward.

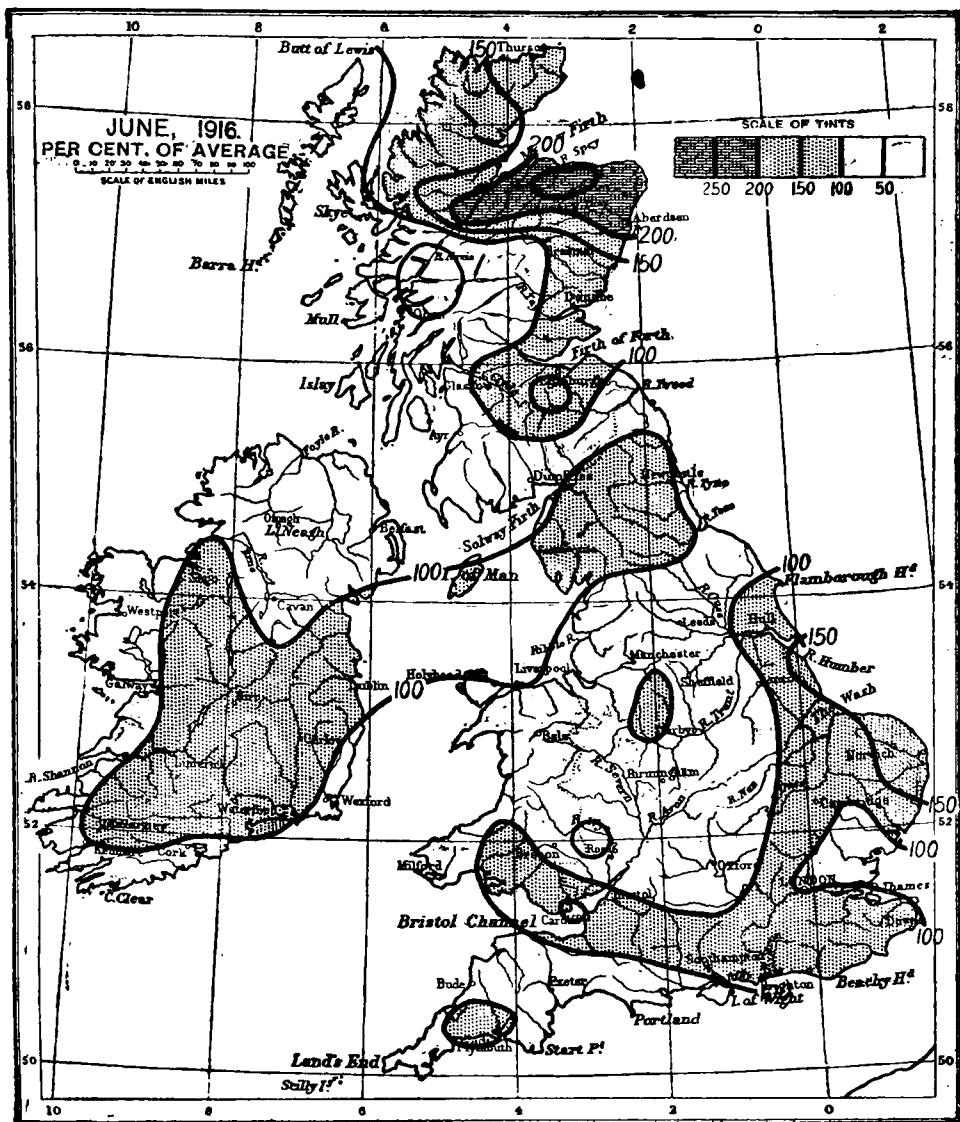

In scarcely any part of Scotland was the fall less than 3 inches.

The rainfall was below the average only in Cornwall and Devon, and in an irregular belt running northward from Hampshire to Yorkshire and thence south-eastward to Essex. The excess of rainfall was greater than 100 per cent. around the northern part of the Irish Sea, in the east and north of Ireland, and the west of Wales and Scotland. An equal excess occurred on the south shore of the Moray Firth.

All divisions of the country showed an excess, only 8 per cent. in the case of England, but 52 per cent. for Wales, 51 per cent. for Scotland, and 82 per cent. for Ireland. The British Isles, as a whole, had an excess of 43 per cent., greater than in any month, except October and February.

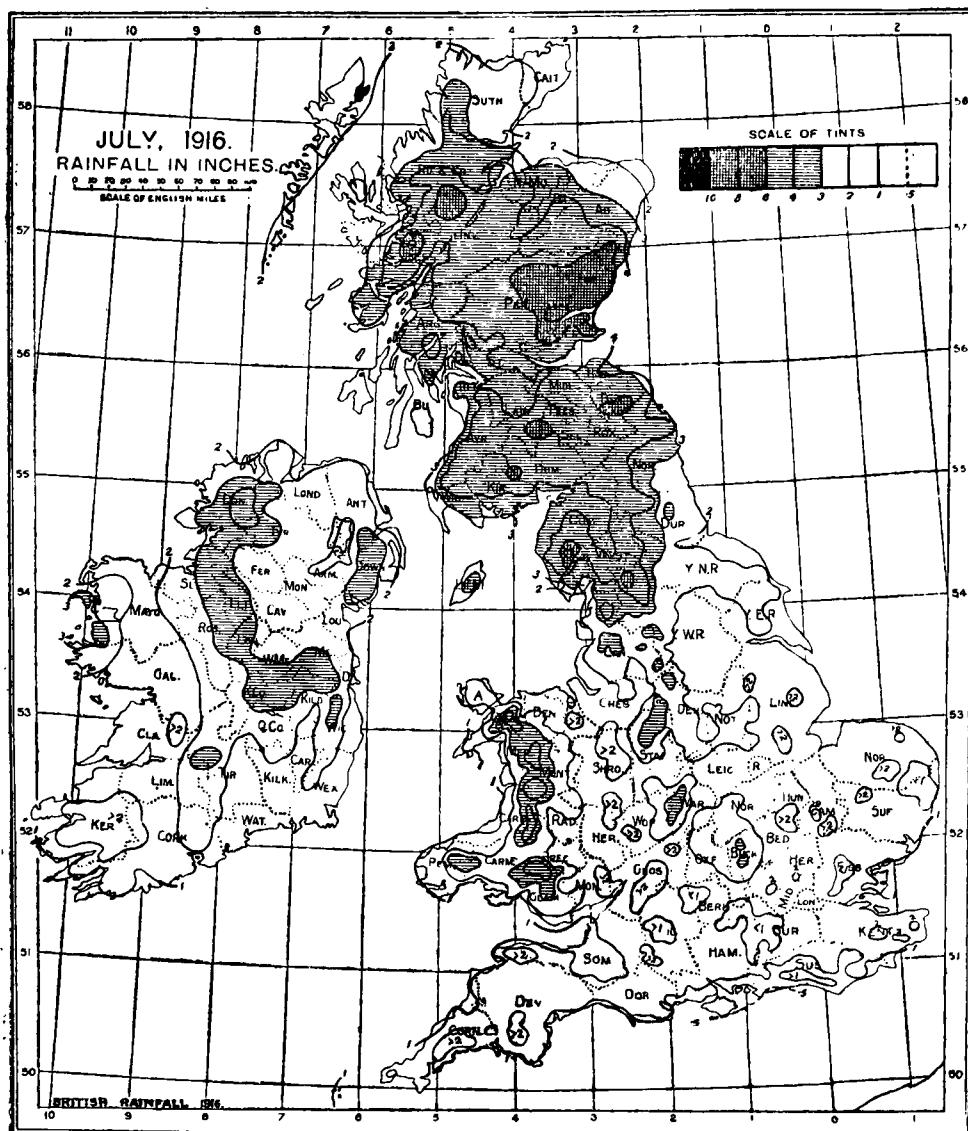

June was signalized by a unusually low temperature and deficient sunshine associated with much east wind and the movement of several depressions through the North Sea ; the result was to give high rainfall on the east coast, which was specially marked on the south shore of the Moray Firth, where parts of Nairn, Moray and Banff had more than 8 inches, being wetter than any part of the west of Scotland. Isolated patches of 6 inches occurred in the north-west of Scotland, the Lake District and Wales. Rainfall less than 2 inches was uncommon, but appeared at intervals round the Irish Sea, and along the west coast of Scotland. A broad irregular belt meandered across central England from the Mersey estuary to the Tees, and narrow strips ran inland from the Thames estuary,

Southampton Water, and the Dorset coast. In Ireland few places had less than 2 inches and fewer more than 4 inches.

The greater part of England, Wales and Ireland varied but little from the average. The best marked contrast was that between the east and west of Scotland, a patch showing an excess of more than 150 per cent. in Banffshire, contrasting with one showing a deficiency of 50 per cent., in the north of Argyll.

The large divisions were closer to the average than in any other month. England had an excess of 2 per cent., and Scotland of 8 per cent., Wales had a deficiency of 2 per cent., and Ireland of 5 per cent., the British Isles, as a whole, being nearly normal, with an excess of 2 per cent.

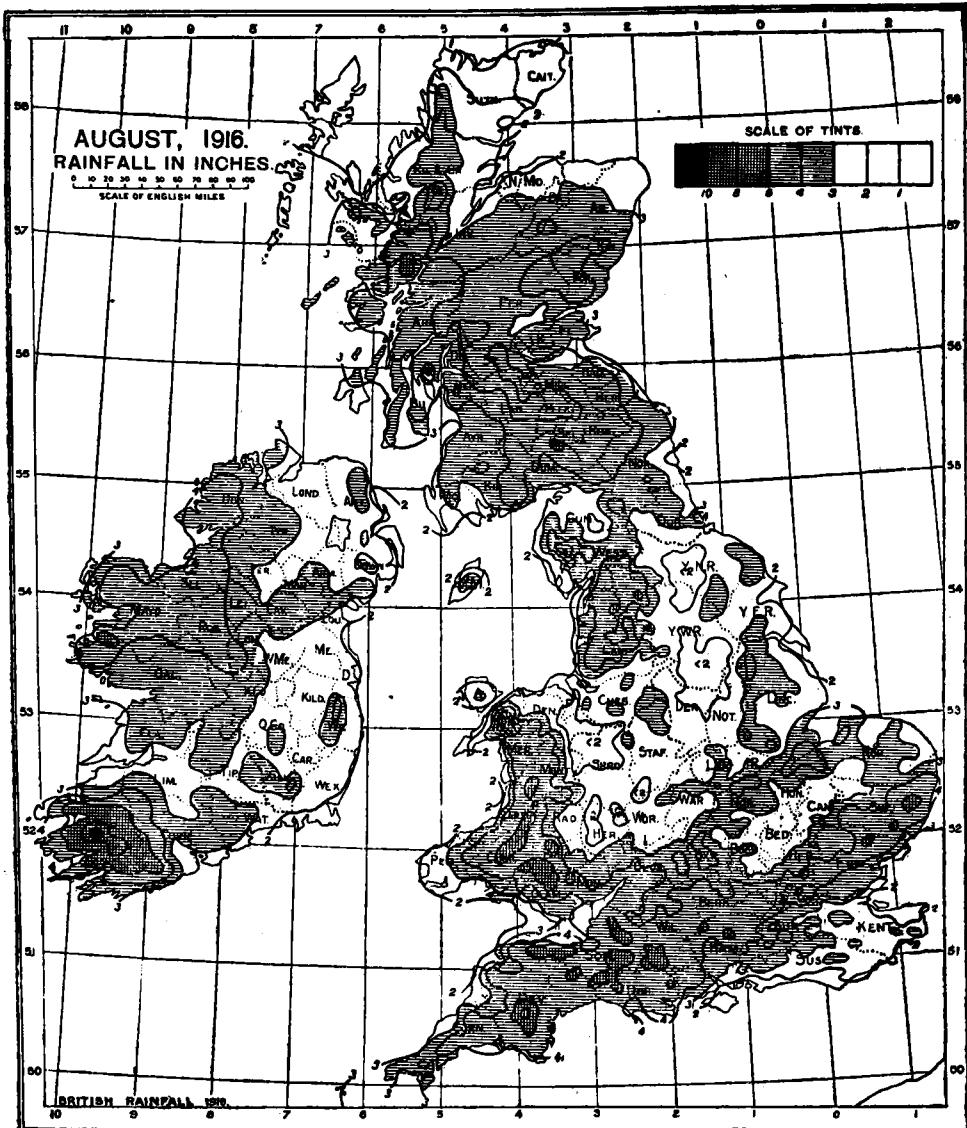

July was cold and gloomy over most of the country during the first half, and the rainfall was dominated by a depression which passed north-eastward on the 7th and 8th, with heavy rain in the east of Scotland, which, with the exception of the extreme north of England and the centre of Wales, was the only part with as much as 4 inches of rain. More than 6 inches fell at several points in Scotland, especially round the Firth of Tay and northward almost to the border of Aberdeenshire. Close to Perth more than 8 inches of rain fell. The Outer Hebrides and the extreme north of Scotland had less than 2 inches of rain, and the greater part of England had less than that amount, diminishing to less than 1 inch in isolated patches in the south, and touching half an inch

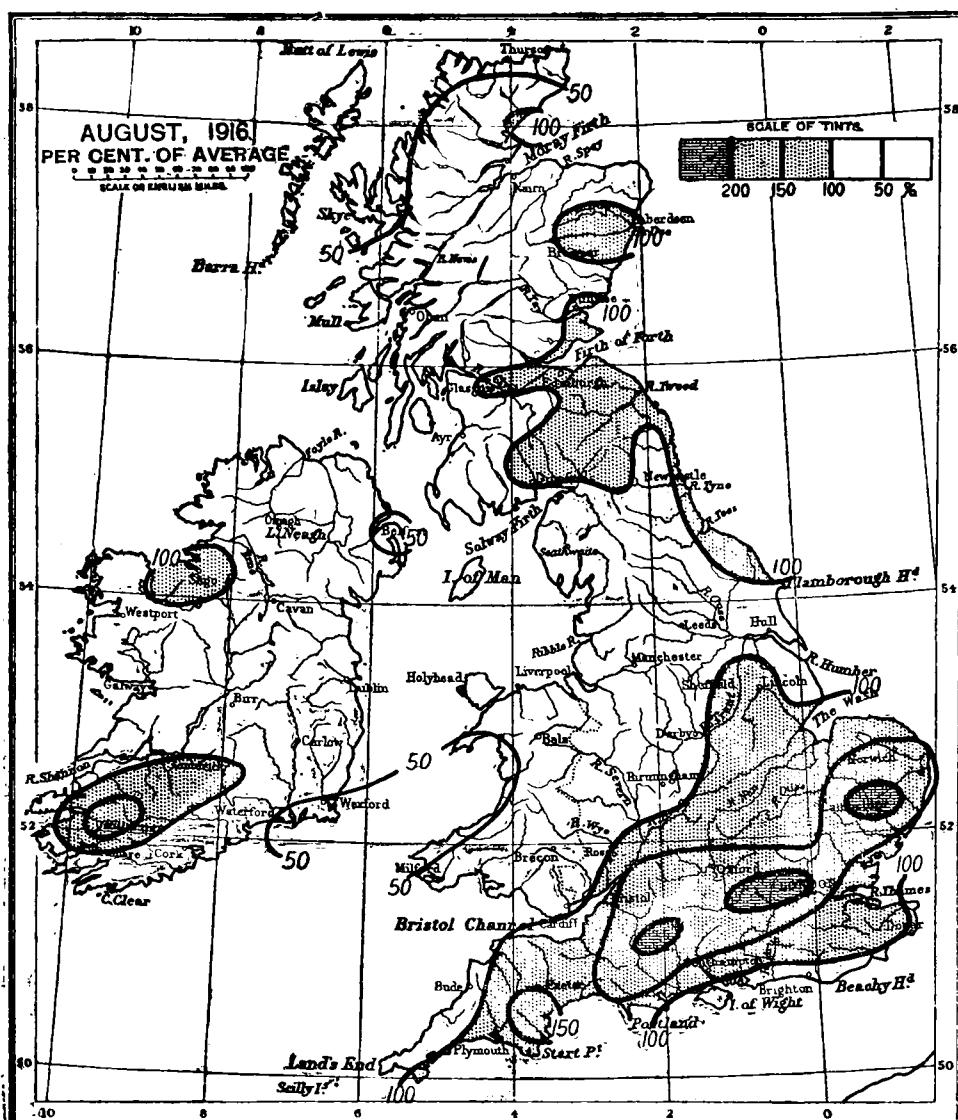

on the extreme south coast. Most of Ireland had less than 3 inches.

More than twice the average fell in the east of Scotland, and the proportion fell off with almost perfect symmetry on all sides reaching the average along a line running south of the Moray Firth, east of Loch Lomond, and north of the Solway, while less than half the average fell all round the British Isles, in Caithness, the west of Ireland, the south-east of Ireland, the west of Wales, the south and the south-east of England.

It was the driest month of the year in England and Wales, with deficiencies of 31 and 39 per cent. respectively. In Ireland the deficiency was 32 per cent., September being drier, while in Scotland there was an excess of 17 per cent. The British Isles, as a whole, had a deficiency of 18 per cent.

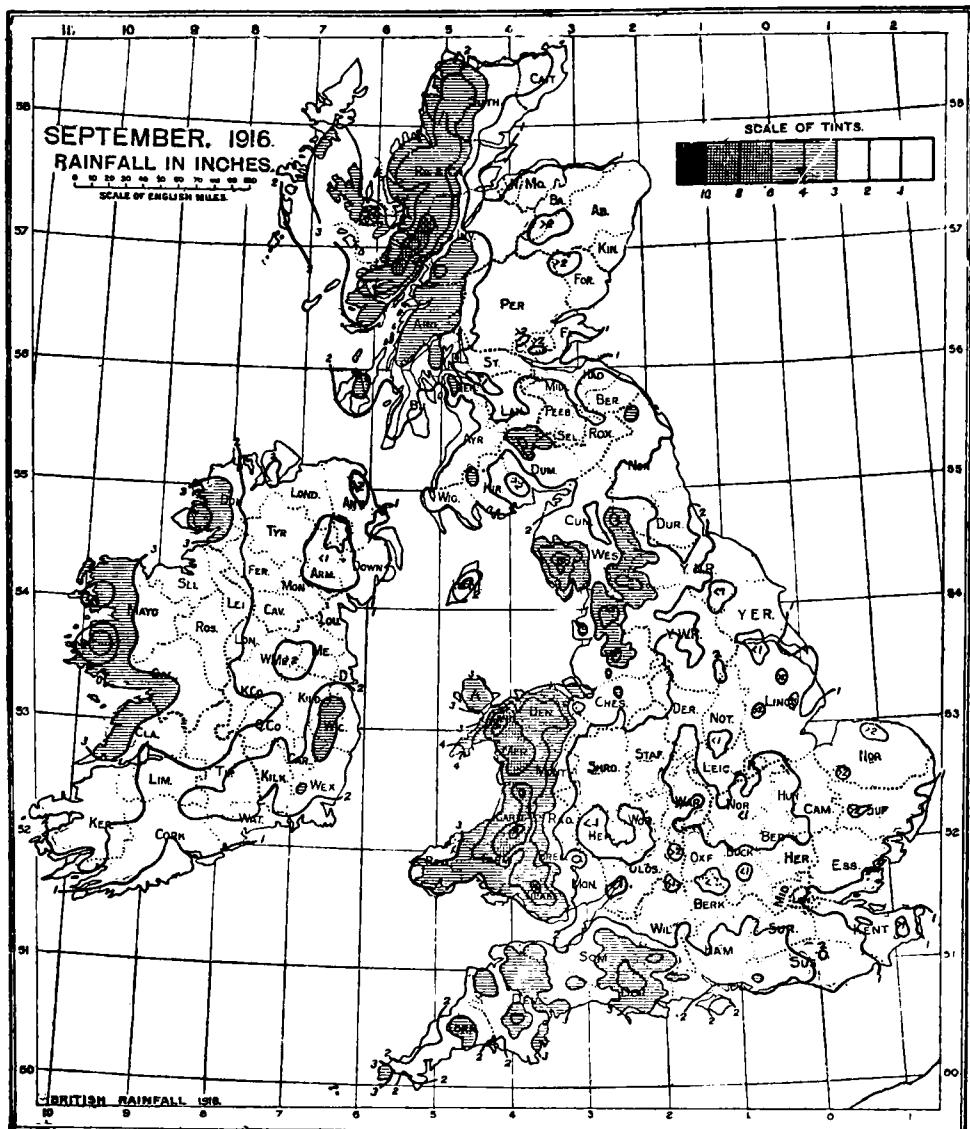

August saw the end of a widespread drought, which terminated on the 12th, after which date a succession of cyclones brought unsettled weather and rain. The dominant feature was the widespread heavy rain of the 29th, which accounts for the extensive strip of more than 4 inches rising in parts to more than 6 inches (and in Dartmoor to over 8 inches) which runs from Cornwall to Suffolk. Equally heavy rain extended through the whole of central Wales and also occurred in the Lake District as well as in the south and west of Scotland and the south-west and north-west of Ireland. Except at intervals along the coasts and at a few inland places between Hereford and Yorkshire, no place had less than 2 inches.

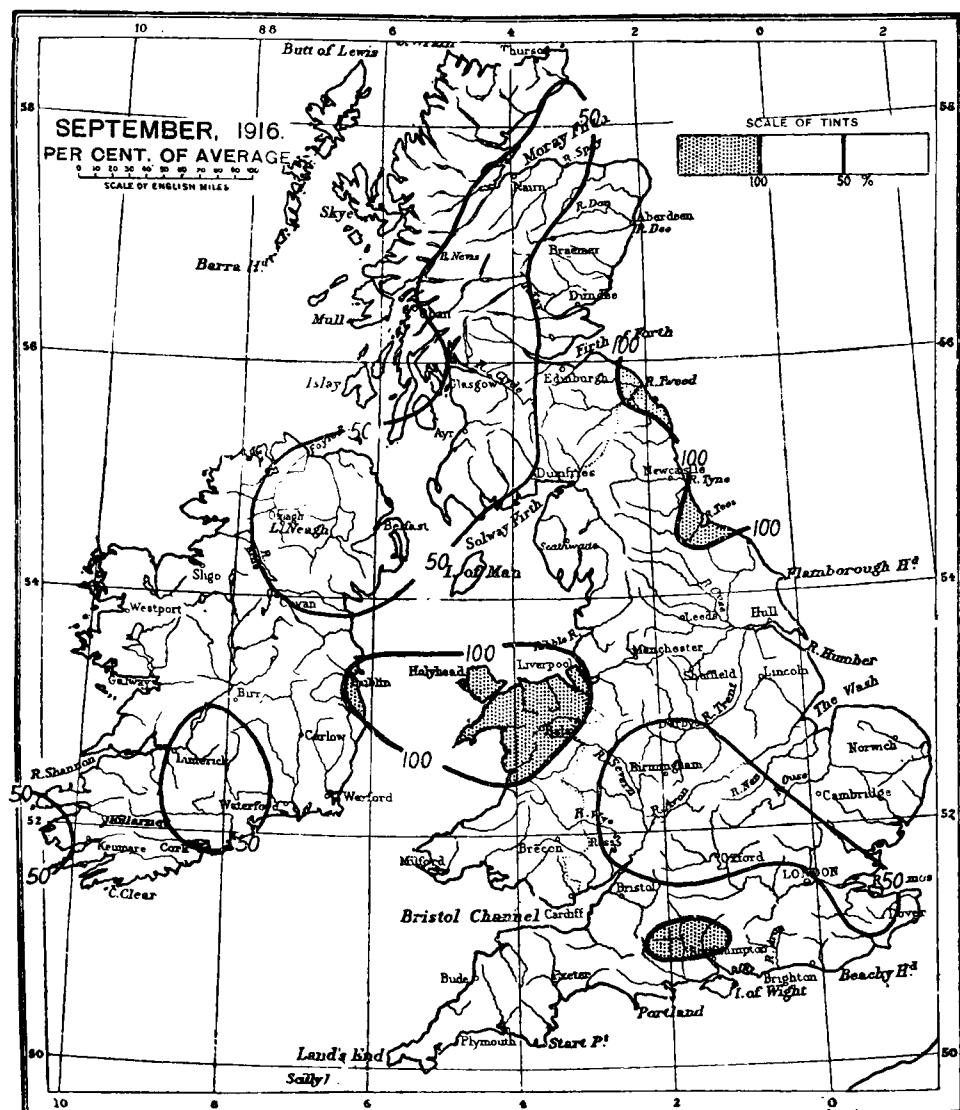

Over most of the British Isles the rainfall was below the average, and there was a deficiency of more than 50 per cent. along the north and west of Scotland and along the west of Wales and at two points in the east of Ireland. The largest area with more than average rainfall spread northeastward across England from Cornwall, and in the axis of it there were three patches in which the excess was greater than 100 per cent. Other areas of moderate excess occurred in the south and east of Scotland and in the west of Ireland.

The general rainfall of England was 11 per cent. above the average, but all the other divisions were dry, Wales having a deficiency of 31 per cent., Scotland of 20 per cent., Ireland of 16 per cent., and the British Isles, as a whole, of 9 per cent.

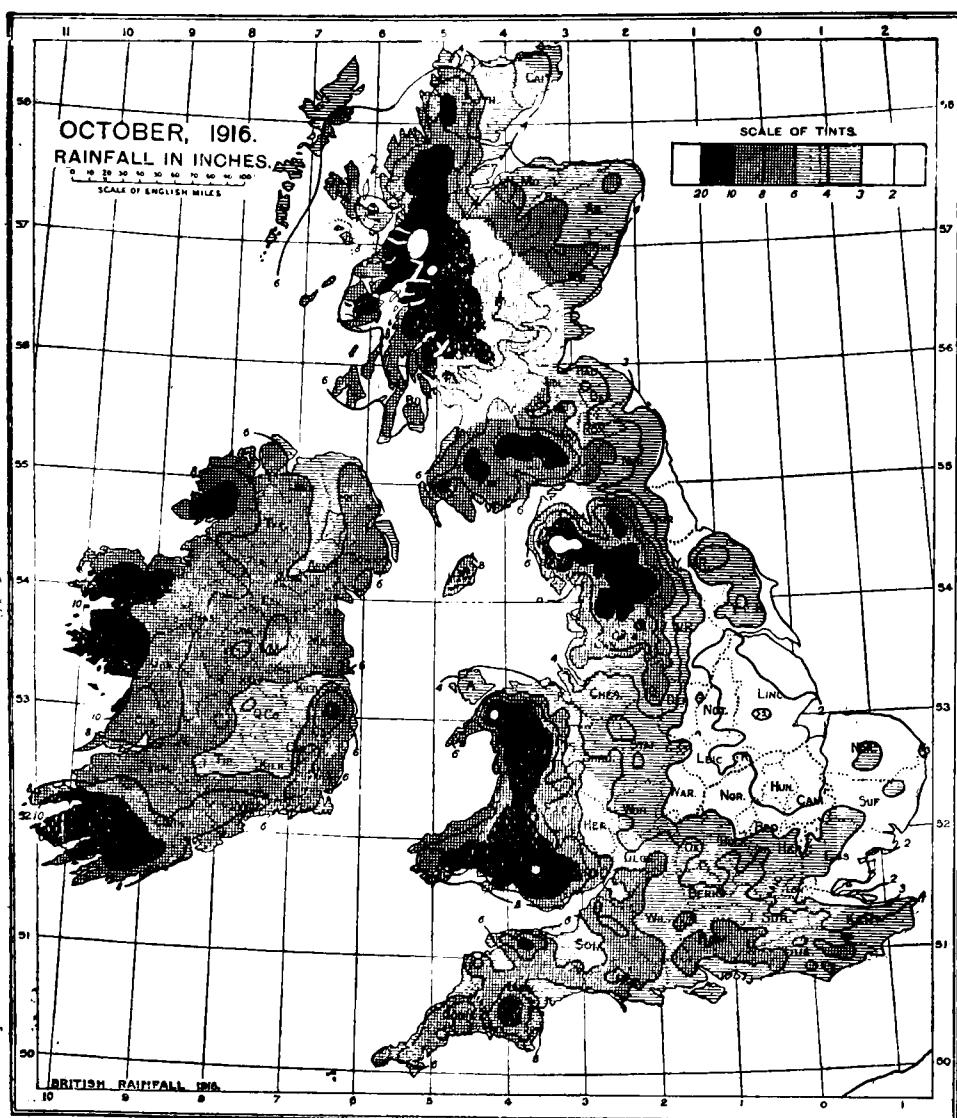

September was relatively the driest month of the year, the only severe and widespread rain which occurred lying to the left of the track of a depression which crossed England on the 3rd from west to east. The rainfall exceeded 3 inches only in the west, where falls of 6 inches and more occurred in Wales, the Lake District, the West Highlands, and in Connemara. By far the larger part of Great Britain and Ireland had less than 2 inches of rain, and there were many isolated patches where less than 1 inch fell, but there was nowhere so little as half an inch.

Rainfall was appreciably above the average only in the north of Wales and along the coasts of Northumberland and Durham, and it fell to less than half the average along the greater part of a broad strip extending

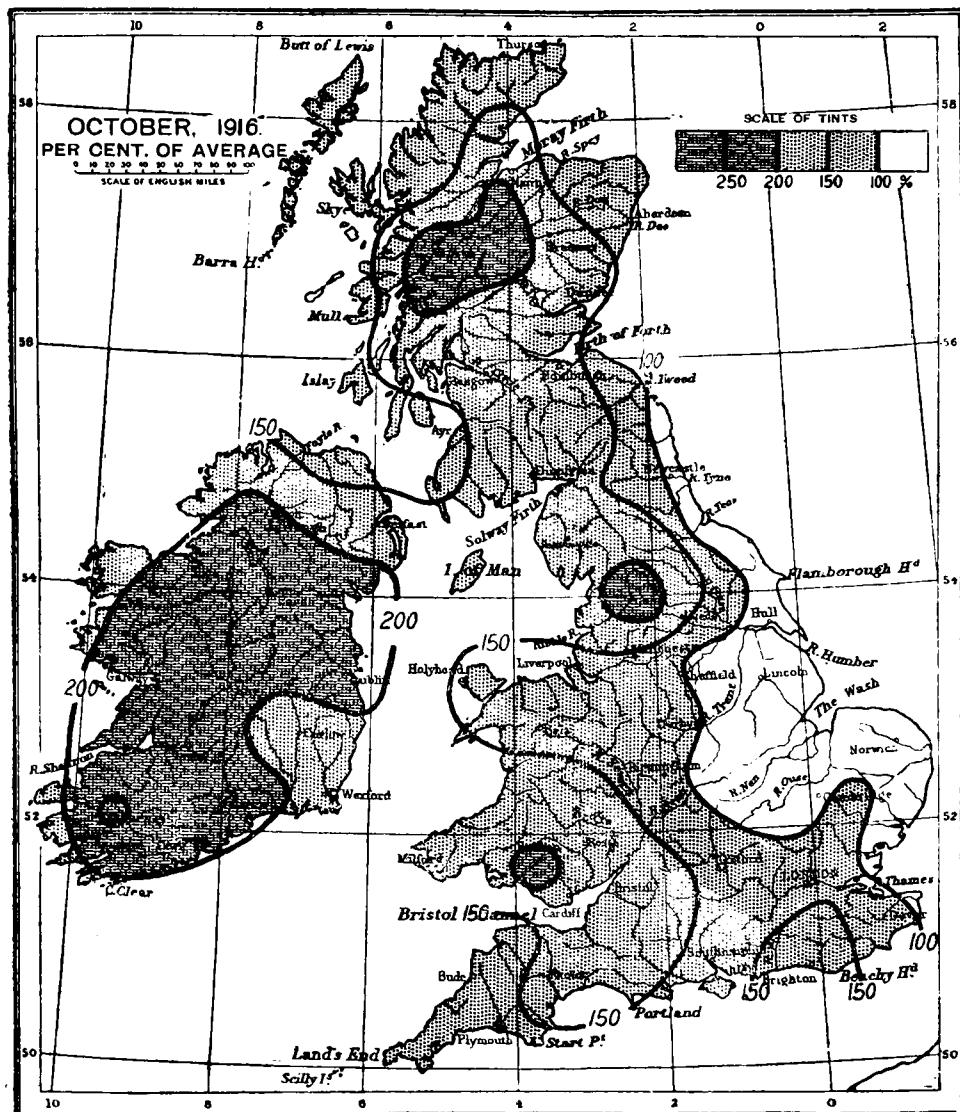

from the south-west of Ireland to the Moray Firth, and also in a large area of the English Midlands, with an extension to the mouth of the Thames. In parts of both these areas rather less than a quarter of the average fell.

Wales was the least dry of the large divisions, having a deficiency of only 9 per cent., England had a deficiency of 28 per cent., being thus almost as dry as in July. Scotland and Ireland were drier than in any other month, the deficiencies being 44 and 43 per cent., respectively, while for the British Isles, as a whole, the month was the driest of the year, with a deficiency of 35 per cent. The tendency of September to be one of the driest months has increased in recent years.

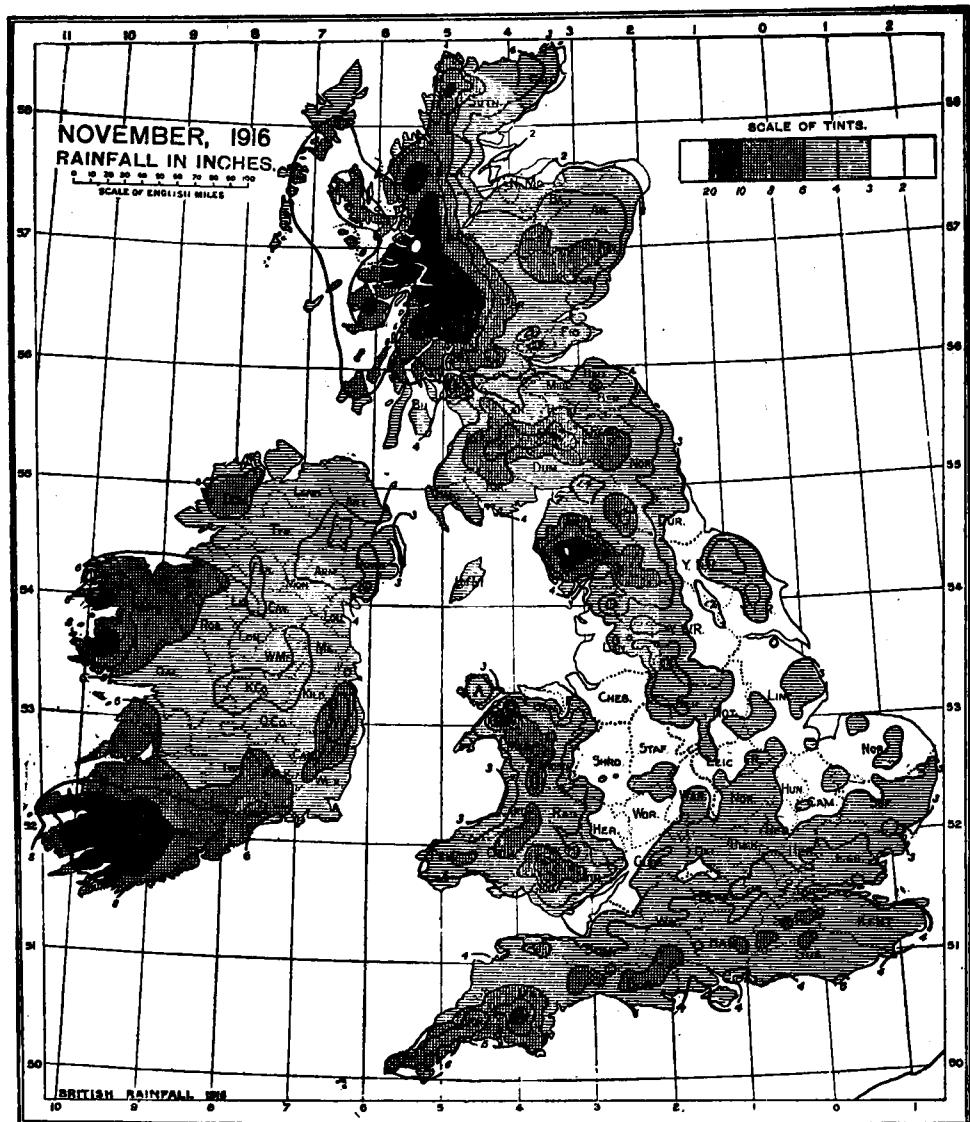

October outdid its reputation as the wettest month of the year, rain in most parts of the country being frequent and heavy as the result of the passage of many depressions. In some parts of Ireland rain fell on 31 days. Less than 2 inches was recorded only in the counties surrounding the Wash and along the Thames estuary, most of the country had more than 4 inches, and very large tracts in England, the greater part of Scotland, and almost the whole of Wales and Ireland, had more than 6 inches. Extensive areas in all four divisions had more than 10 inches of rain, and in South Wales, North Wales, the Lake District, and the West Highlands, more than 20 inches were recorded. In the last named district this was largely due to the unprecedented rainfall of the 11th.

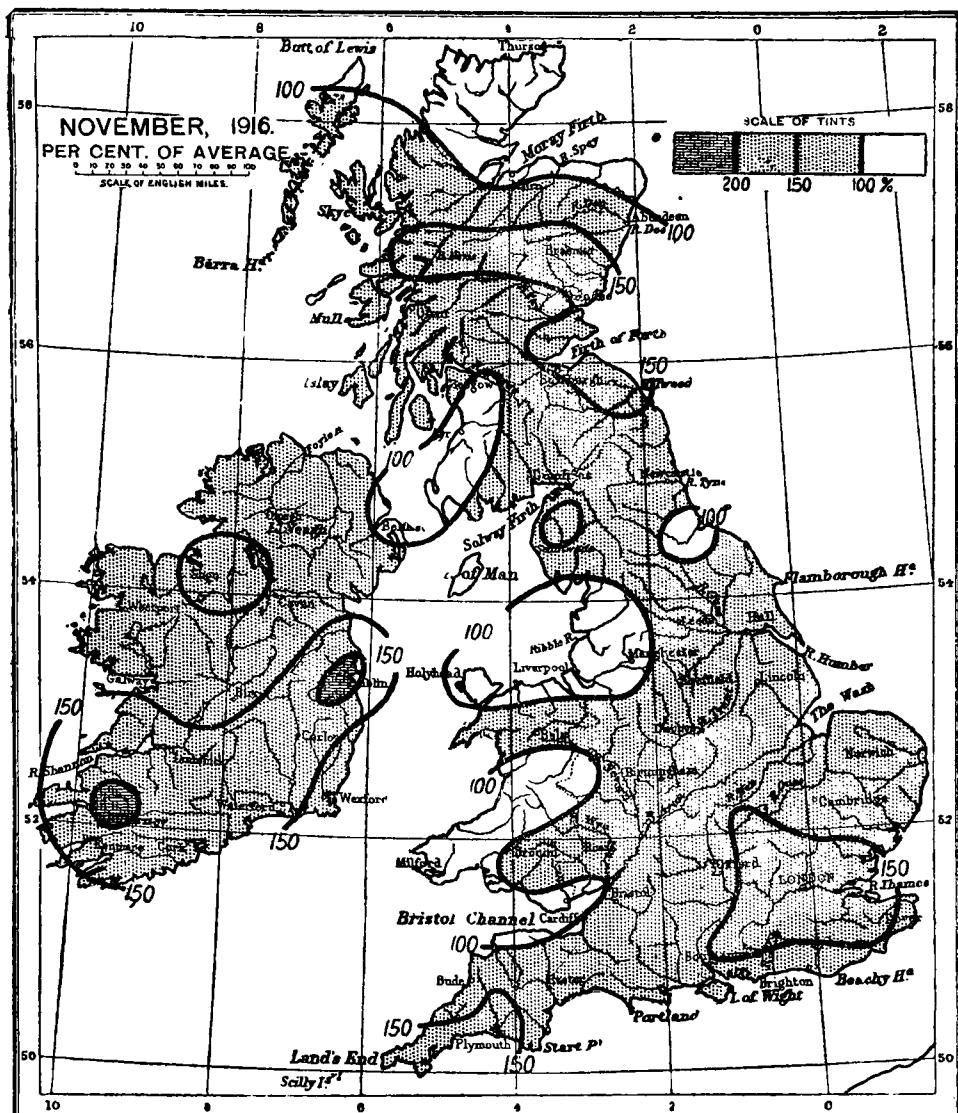

The rainfall was less than the average only in the east of England, and more than twice the average amount fell throughout almost the whole of Ireland, in a small area in South Wales, in the central Pennines, and throughout the West Highlands.

The excess of rainfall in England was 35 per cent., in Wales, 65 per cent., in Scotland, where the month was the wettest of the year, 62 per cent.; but Ireland had the unenviable distinction of a general rainfall more than twice the average, the excess being 106 per cent.; for the British Isles, as a whole, the excess was 62 per cent., the month ranking second only to February for wetness, relative to the average, while the actual rainfall was much greater.

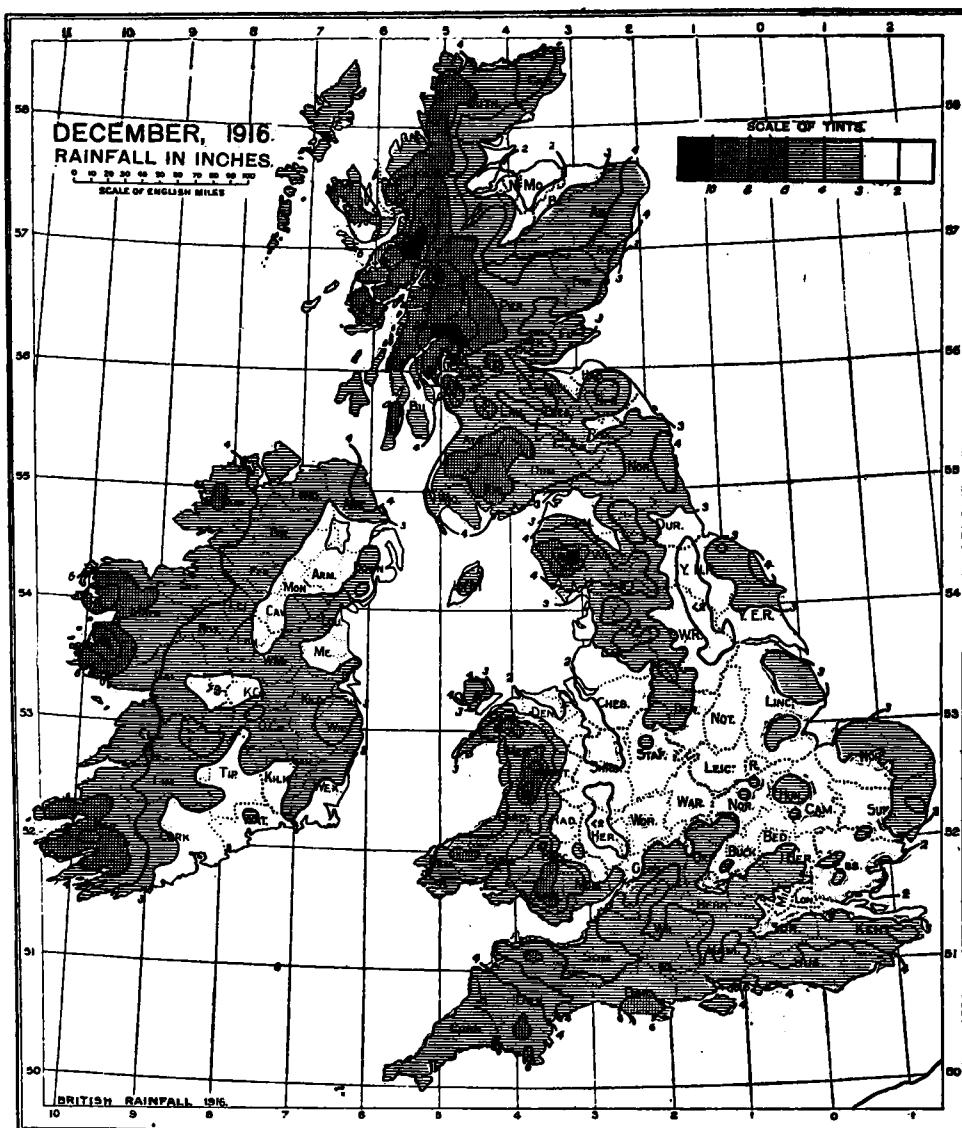

November was very stormy and the distribution of rainfall closely resembled that of October, large areas having more than 10 inches in the south-west and west of Ireland, the Lake District, and the west of Scotland, though the fall was generally lighter than during October especially in Wales. Very heavy falls for the locality occurred in the south of England, where more than 4 inches fell from Cornwall to the mouth of the Thames, culminating in a series of areas with more than 6 inches which occurred in all the southern counties. More than 6 inches also fell in Scotland as far east as Kincardineshire and Haddingtonshire. The only parts of the country with less than 2 inches were round the Moray Firth and in the Vale of York.

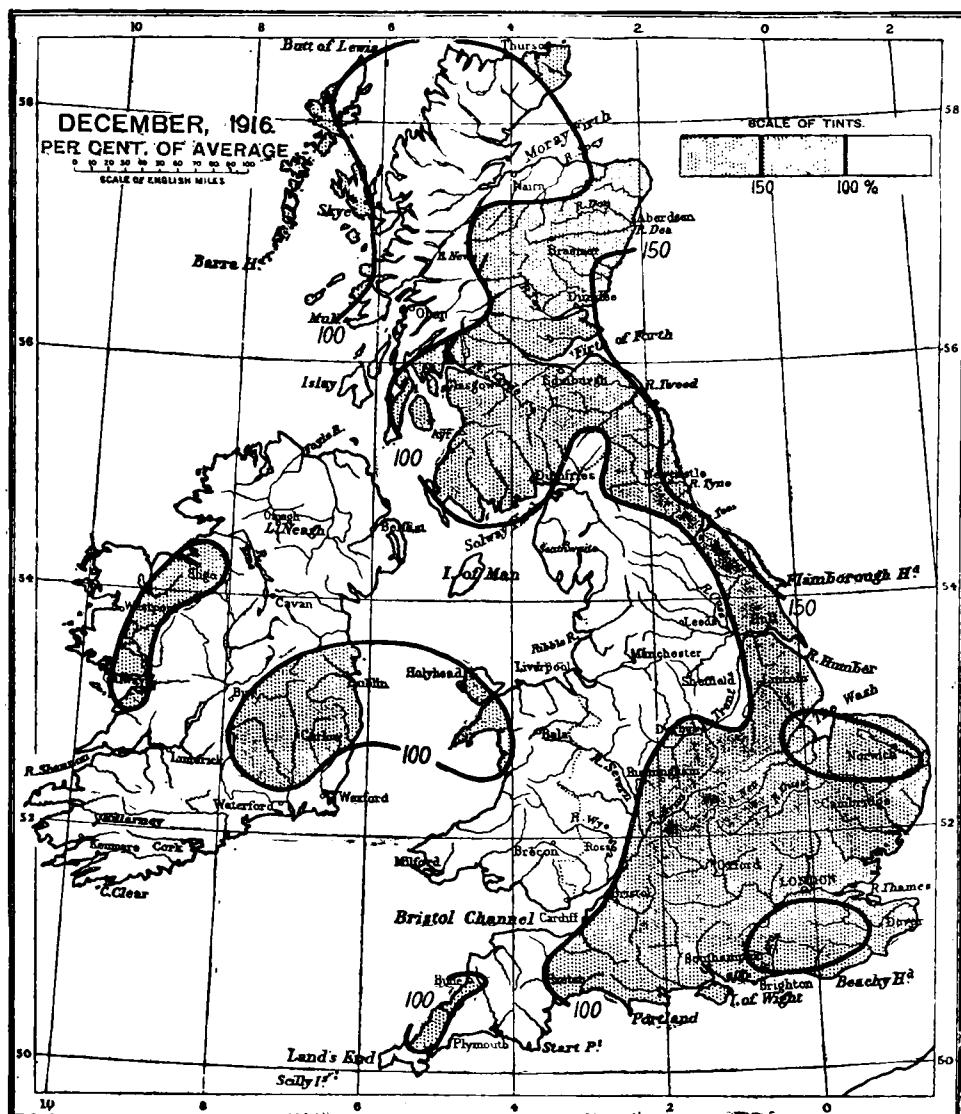

The rainfall was below the average in the north and in the south-west of Scotland and throughout the greater part of Wales and Lancashire. Over the rest of the country the rainfall was excessive, the excess being greater than 50 per cent. round London, in the south of Cornwall, in the east and centre of Scotland, and markedly so in the south of Ireland, where Cos. Kerry and Dublin had more than twice the average fall.

Except in Wales, where there was a deficiency of 4 per cent., the whole country showed large excesses. In England and Scotland, 31 per cent., and in Ireland, 45 per cent., while the British Isles as a whole, had 30 per cent. more than the average.

BRITISH RAINFALL, 1916.

December was dull and foggy, but had much less rain than the two preceding months. This was especially noticeable in the west where the areas with more than 10 inches were very small, and 6 inches fell over considerable areas only in the west of Ireland and Scotland though there were small patches in Wales, the Lake District and the south-west of England. The rainfall was less than 2 inches in Morayshire and round the estuaries of the Thames and Mersey, in the Vale of York, in Shropshire and Herefordshire. Falls exceeding 4 inches were again prevalent over the southern tier of counties in England, and occurred also at intervals along the east coast of Great Britain.

Except for the south-western counties of Scotland and narrow strips in the west of Ireland and the north-west of Wales, it may be said generally that the rainfall was decidedly below the average in the west both of Great Britain and Ireland, and even more decidedly above the average in the east, where at many points on the coasts of Scotland and England the excess was greater than 50 per cent.

England and Scotland were very close to the average in rainfall, showing excesses of only 5 and 2 per cent. respectively, while Wales had the large deficiency of 23 per cent. and in Ireland the rainfall was 12 per cent. below the average; the British Isles, as a whole, showed a deficiency of 3 per cent.

Ireland. Mean of 66 stations

BRITISH ISLES. Mean of 299 stations

SEASONAL RAINFALL, 1915-1916.

IN dealing with seasonal rainfall we have pursued the same method as in previous years and publish the usual tables with statistics for 103 selected stations. These figures were used in the preparation of maps of the winter half-year, the summer half-year, and the seasonal year ending September, 1916, and we much regret that it has been found impossible to reproduce them in this volume without greatly delaying its appearance.

During the winter half-year, October, 1915, to March, 1916, the rainfall over the country was excessive in all the large divisions taken as a whole, but showed a deficit in various districts. The largest and most intense of the dry areas was in the west and north-west of Scotland, where the deficiency reached nearly 20 per cent. at some stations affected by the drought which prevailed in the West Highlands during the last three months of 1915. Deficient rainfall occurred also in the north-west of England, and in the north and south of Ireland. There were three large areas of great excess situated respectively towards the east of England, Scotland, and Ireland, and the wettest part of each showed excesses greater than 50 per cent. In the English area excesses of more than 50 per cent. occurred over the whole of the Thames Valley, a tongue stretching westward into Herefordshire and Worcestershire, and another embracing a considerable portion of the south-east of England, including the counties of Sussex and Hampshire. A second and much smaller area, showing an excess of more than 50 per cent., occurred in the Midlands, centreing round Derby. The wettest area in Scotland centred round Braemar, where there was an excess of 55 per cent. In Ireland a restricted area in the vicinity of Dublin had an excess of 50 per cent., and over a considerable part of the east of Ireland the excess amounted to more than 20 per cent.

The general rainfall of England for the winter half-year showed an excess of 27 per cent., that of Wales, 15 per cent., of Scotland, 6 per cent., of Ireland, 12 per cent., and of the British Isles, as a whole, 16 per cent.

In the summer half-year, from April to September, 1916, the distribution of the rainfall in relation to the average again showed wide deviations

from the normal, especially on the dry side. Speaking broadly, the east coasts of the country had a rainfall above, and the south and west coasts a rainfall below the average. The wettest area was roughly the eastern half of Scotland, the greater portion of which had an excess of 20 per cent., rising to over 40 per cent. in parts of Forfar and Midlothian. The heavy rainfall covered the border counties and the area of excess extended into the northern part of England. A considerable part of the east of England, including the counties of Lincoln, Norfolk, Suffolk, and extending in a south-westerly direction into Surrey, had a general excess of about 10 per cent. The greater part of Ireland had a rainfall in excess of the average, but the excess was above 20 per cent. only in the north-west, in the counties of Donegal and Sligo, and at one point in Kerry. The greatest deficiency occurred in Cornwall, where it was more than 30 per cent. below the average. Next to this came portions of the south-coast and Pembrokeshire, and a large portion of the Midlands, where the deficit was more than 20 per cent. Practically the whole of the West Highlands and the north of Scotland had a rainfall under the average, as had the western and southern portions of Ireland, but the deficit scarcely anywhere exceeded 15 per cent. In England and also Wales the general deficiency was 9 per cent., but in Scotland and Ireland the rainfall was so nearly equalized that the excesses were 3 per cent. and 1 per cent. respectively. For the British Isles, as a whole, there was a deficiency of 3 per cent.

The combined seasonal year, ending with September, 1916, shows a much less extreme distribution of excess and deficiency of rain than either of its component halves. All the great divisions show an excess, that of England being 10 per cent., Ireland 7 per cent., Wales and Scotland 5 per cent., while the general rainfall of the British Isles as a whole was 7 per cent. in excess. The three wettest areas indicated in the map for the seasonal year naturally fall in those parts of the country which show an excess of rain both for the winter and summer half-year, viz., the east of Ireland, the east of Scotland, the Thames Valley and East Anglia. The three driest areas in the annual map likewise lie in the regions where the deficit prevailed in both half-years. Of these the largest was in the west and north of Scotland, in which the maximum deficiency reached nearly a fifth of the average at Fort William and in the isle of Mull. The areas covered by an excess of 20 per cent. in England and Scotland was of equal extent in both countries, but in Ireland an excess of this amount occurred only in a small area centred around Dublin.

Seasonal Rainfall, 1915-1916, in Relation to the Average, 1875-1909.

THE RELATION OF THE TOTAL FALL OF RAIN IN 1916 TO THE AVERAGE

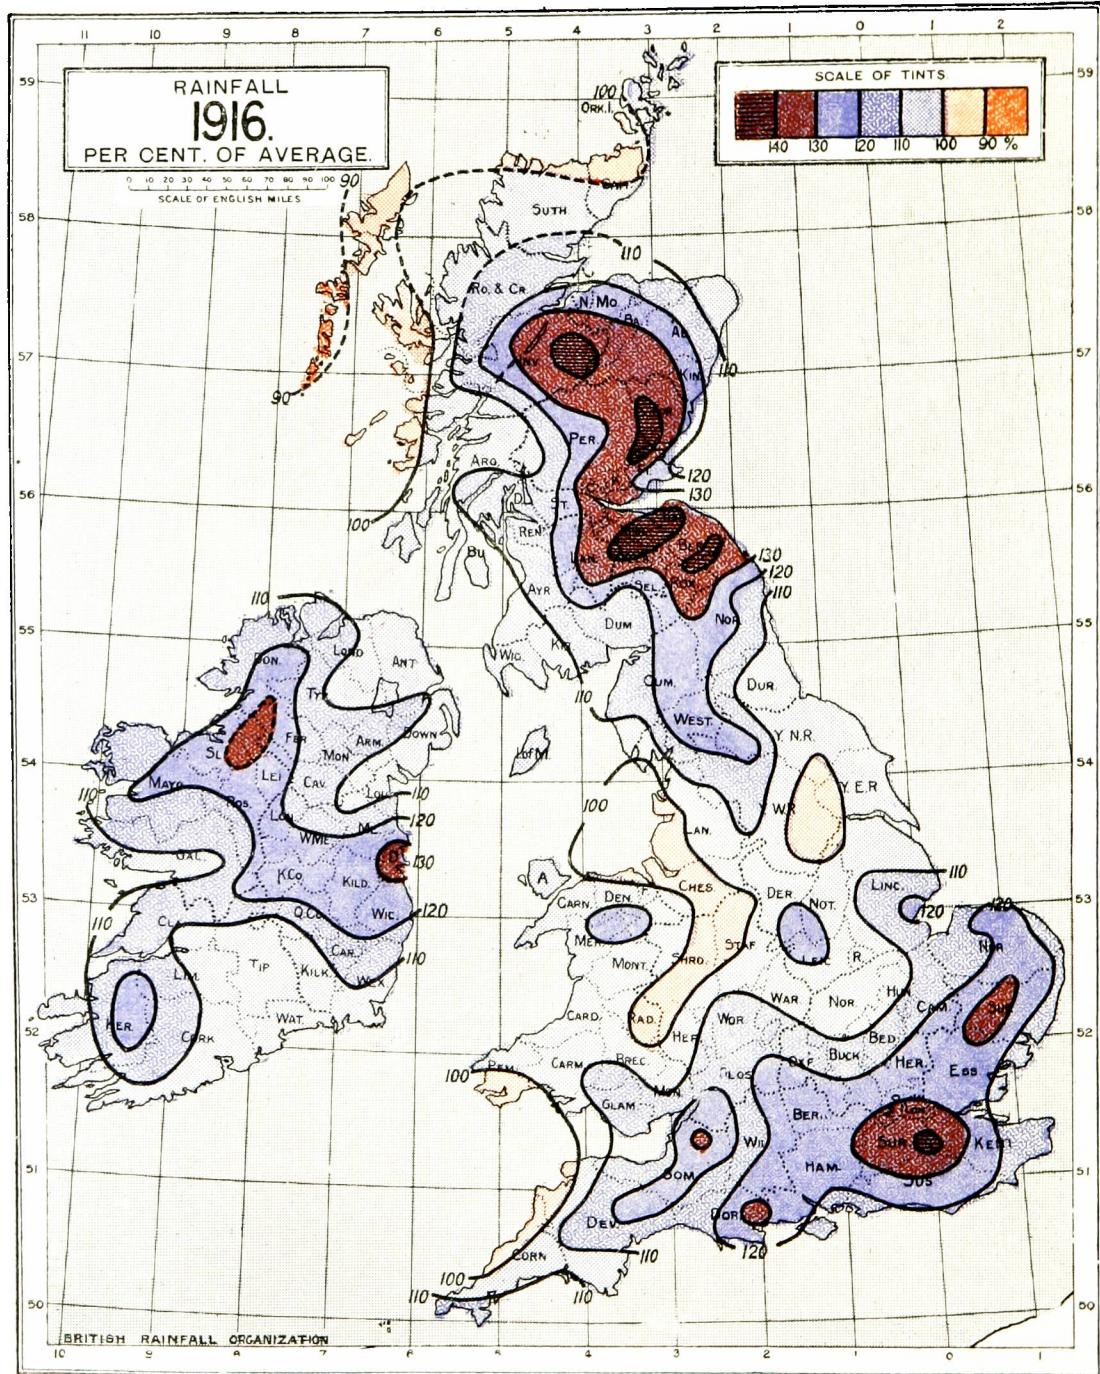

THE number of rainfall stations with records long enough to yield an average of 35 years is now very considerable ; but the distribution of these stations is unequal, and it is necessary in order to yield figures representative of wide areas to select stations which are as nearly as possible equidistant. As the weakest part of a chain is its strongest part so the thinnest part of the system of long-period stations must be adopted as the thickest part of a uniform system. Following this rule we have selected the 207 stations which are given in the long table at the end of this section. It gives the average rainfall for the ten years 1900-1909 as the last completed decade, a period sufficiently recent to be covered by the greater number of the rainfall records now running, next the average for the 35 years 1875-1909, which may be taken as the normal value, the figure being arrived at in a few cases by computing values for a few missing years. The rainfall in 1916 is then given followed by the difference from the 35 years' average first in inches and then as a percentage of the average. The mean of the values in each of the natural divisions gives a close approximation to the general rainfall and a still closer approximation to the general difference from the average in those areas, and these are set out in the following abstract :—

ABSTRACT.

COUNTRIES.	No. of Records utilized.	Average.	Average.	1916.	Diff. from Average 1875-1909.	
		10 years 1900-09.	35 years 1875-1909.		Amount.	Per cent.
England.....	88	32·24	33·14	37·58	4·44	+ 13
Wales.....	17	46·88	47·25	50·45	3·20	+ 7
England and Wales.....	105	34·61	35·42	39·66	4·24	+ 12
Isle of Man	1	41·35	41·55	44·95	3·40	+ 8
Scotland	57	46·23	45·18	52·46	7·28	+ 16
Ireland	44	40·79	40·59	46·27	5·68	+ 14
British Isles	207	39·16	39·24	44·62	5·38	+ 14

The result is to show that the year was wet for each of the great divisions, wettest in Scotland, with an excess of 16 per cent., and least wet in Wales, with an excess of only 7 per cent. Ireland, as very frequently

RELATION OF RAINFALL IN 1916 TO THE AVERAGE OF 1875-1909.

The area coloured Red had rainfall below the average, that coloured Blue had rainfall above the average.

happens, had the same excess, 14 per cent. as the British Isles as a whole.

The following short table compares the year 1916 with the six previous years for which the same average has been used. Of these only 1912

Comparison of the Total Rainfall 1910-1916 with the average 1875-1909.

Year.	England.	Wales.	Eng. and Wales.	Scotland.	Ireland.	British Isles.
1910	111	116	112	103	108	109
1911	94	101	96	101	99	98
1912	123	119	122	111	108	115
1913	96	109	98	96	107	99
1914	109	110	109	103	108	107
1915	110	105	109	92	102	102
1916	113	107	112	116	114	114

showed a greater excess of rainfall, and the difference was so slight that the two years may be said to have been practically equally wet. It will be noticed, however, that England and Wales were wetter in 1912 than in 1916, while Scotland and Ireland were wetter in 1916 than in 1912. Wetter years were experienced in 1903 and in 1882, also in 1877 and 1872; but there is reason to believe that 1916 was perhaps wetter than any, except those, in the past half century. It is interesting to notice that of the seven years compared in detail in the foregoing table only two had rainfall below the average; 1911, with a deficiency of 2 per cent., and 1913, with a deficiency of 1 per cent. It will be observed that on the whole the years have been alternately wetter and drier than the year before, the wetter years, 1910, 1912, 1914, and 1916 averaging 11 per cent. above the average, while the drier years, 1911, 1913 and 1915 were just equal to the average. Taken as a whole they present a remarkable period of high rainfall, the mean excess being 6 per cent. for the British Isles. In Wales all seven years were above the average, with a mean excess of nearly 10 per cent.

The long table of rainfall in 1916 compared with the 35 years' average shows only 13 stations out of the 207 with less than the average fall, and it is very rare to find a year with fewer; for however wet a year may be there is always some part of the country with a deficient fall.

The coloured map shows in a red tint the few small areas where the rainfall was below the average. These are four in number, *viz.*, (1) the Hebrides and the extreme north of Scotland, (2) the north-east coasts of Devon and Cornwall and the south-west tip of Wales, (3) a strip extending from the extreme north of Wales and the coast of Lancashire, through Cheshire, and southward to Herefordshire, (4) a detached patch

mainly in the east of the West Riding of Yorkshire. Only in the west of Scotland, did the deficiency amount to as much as 10 per cent. of the average.

The three English dry areas mark out a belt of relatively low rainfall extending from the Bristol Channel to the Yorkshire coast, dividing Great Britain into a south-eastern and a northern portion, in each of which the rainfall was relatively high. A third very wet area filled central Ireland.

The south-eastern wet area showed an excess of more than 10 per cent. across the whole of the south of England, from Dartmoor to Lincolnshire, and the greater part of this region, especially towards the south and east, had an excess of over 20 per cent., culminating in four symmetrically disposed patches centred respectively in the Mendips, the New Forest, Surrey and Suffolk, where the excess attained the unusual amount of more than 30 per cent., and in the heart of the largest of these patches a portion had an excess exceeding 40 per cent., this being relatively the wettest part of England for the year. The northern wet area was larger and even more remarkable, an excess of more than 10 per cent. being recorded from Yorkshire throughout the north of England and nearly the whole breadth of Scotland to the borders of Sutherland; within this, more than 20 per cent. of excess was experienced from Westmorland to the Moray Firth, and a great central core, with an excess greater than 30 per cent., filled the east and centre of Scotland from the Tweed to Inverness. In four localities centred on the lower Tweed, the Lothians, Forfarshire, and the middle Spey Valley, the excess was greater than 40 per cent. Thus, while the southern wet area extended from west to east along the south coast of England, the northern wet area extended from south to north along the east coast of Scotland, the rainfall diminishing to the average in the west of the mainland of Scotland and falling still lower in the Western Isles.

In no part of Ireland did the rainfall of 1916 fall short of the average, and the greater part of the country had an excess of more than 10 per cent., a small area in the south-west had more than 20 per cent., and a large tract extending from the east coast, between Wicklow and Drogheda, north-westward, across the centre of the country to Donegal Bay, had also more than 20 per cent. In the east of this region round Dublin, and in the north-west between Sligo and Donegal, the excess was greater than 30 per cent., a very unusual circumstance in Ireland.

The annual map of departures from the average may, of course, be viewed as built up from the twelve maps of monthly departures from the

average which have been described in a previous section, and the influence of exceptionally wet months upon the annual map can be traced in the case of each of the three regions of great annual excess. Bearing in mind the variability in the distribution of monthly rainfall, one would hardly expect to find any resemblance in the successive annual maps, but as we have shown before such resemblances do exist and there are distinct indications of progressive alteration in the distribution of light and heavy rainfall from one year to another. The relation between 1916, 1915, and 1914, is so remarkable that it is worth while to compare the coloured maps in the last two volumes of *British Rainfall* with that in the present.

In Ireland in 1914 there was an extensive wet area in the west and dry strips on the north, south, and especially the east, coasts. In 1915 the wet area had shifted to the centre and east of Ireland, more than 10 per cent. of excess occurring in Sligo, Roscommon, and King's County, and from Wexford to Dublin, and Dublin having more than 20 per cent. excess. In 1916 most of Ireland had an excess of more than 10 per cent. The two areas with over 10 per cent. excess in 1915 were merged in 1916 in one great tract with more than 20 per cent. excess, culminating near Sligo and Dublin in small patches where the excess was more than 30 per cent. Thus the general result was for the wetness to shift eastward and northward between 1914 and 1915 and to intensify in the 1915 positions in 1916. A very similar shifting and intensification of the dry areas may be traced in the maps for 1906, 1907, 1908, culminating in the very dry year 1909.

The distribution of rainfall over Scotland in 1914 was excessive in the centre, some parts of Perthshire having an excess of more than 20 per cent., deficient along the east coast and rather dry also in the extreme west. In 1915 the wet area had moved from the centre eastward to the coast, the wettest portion having shifted from Perthshire to the west of Aberdeenshire and increased in intensity to over 30 per cent. excess, while the whole west of the country was dry. In 1916 the dry area was pushed out westward to the Hebrides, while the wet area seated in the 1915 position had increased greatly both in extent and intensity, the excess at some points nearly reaching 50 per cent. Here, again, we see an eastward march and intensification of regions of excessive rainfall. A similar, though less marked progression, was shown between 1906 and 1910. The arrangement in 1910 resembled that in 1915, but there the similarity ended, the wet and dry areas changing places in 1911 instead of the wet intensifying as in 1916.

In England and Wales an exactly similar shifting to east and north of the southern wet areas may be traced from 1914 onward. In 1914 the wettest patch was in Dorset, where a small area had an excess of over 30 per cent.; in 1915 three large areas with over 30 per cent. excess reached from Dorset to the Thames, two of them with cores showing over 40 per cent. excess, while in 1916 similar areas were centred rather more to the east and north, but there was no marked intensification. Earlier years since 1906, when these comparisons became possible, do not show a clear example of similar progressive changes. It may be noted, however, that a small district in Kent, Surrey and Sussex, has shown an excess of rainfall every year since 1909 inclusive, a period of eight consecutive years.

Such orderly recurrences and progressive changes in the disturbances of the normal rainfall (which results from the interaction of prevailing winds and the configuration of the land), point to meteorological processes which act with a certain regularity for several years at a time and should, when recognized, lead to the possibility of long range weather forecasts of some value. The direction in which to look for these processes seems to us to be the surface circulation of the ocean with the periodical or occasional displacements of the great systems of cold and warm currents.

COMPARISON OF THE RAINFALL OF THE YEAR 1916 WITH THE AVERAGE OF THE PERIODS 1900-09 & 1875-1909.

EXTREMES OF RAINFALL IN 1916.

IN calling attention to the districts of highest and lowest rainfall during the year it is necessary to remind the reader that these can only be distinguished so far as the records which have come into our hands give an adequate representation of the normally very rainy or very rainless districts. The annual extremes of rainfall in each of the great divisions of the British Isles are probably always to be found within fairly well defined regions of no very great extent, and according as gauges are observed in these regions the extreme values for each year will be more or less true for the countries as a whole.

Districts of Greatest Rainfall.

The rainfall of the year did not reach 100 inches in any part of England, except the centre of the Lake District, and even here the area with that amount was rather unusually limited. The largest falls were recorded as usual on the Styne, where three gauges yielded within an inch of 199 inches, the highest giving **199·95 in.** In Wales, 100 inches fell on the highest ridges in Glamorgan, Brecon, Cardigan and Snowdonia, but the last mentioned was the only remarkable area. On Snowdon a number of gauges recorded more than 150 inches, and at Llyn Llydaw **170·89 in.** fell. The rainy areas of Scotland are of much larger extent than those of England and Wales, and the few existing gauges do not adequately represent the variations in the rainfall. The regrettable termination of the observations at the Ben Nevis Observatory leaves us in some doubt as to whether more rain commonly falls on the summit of that mountain than in the Glen Quoich district, and it is possible that other glens in the West Highlands may at times have an equally large fall. In 1916 it appears probable that 100 inches or more fell over several large areas covering a large part of the country between Loch Lomond and Glencarron. The highest falls recorded were round the head of

Loch Quoich, where **187·70 in.** fell at Loan. In Ireland, as far as the available records give any indication, no area received 100 inches except parts of the mountains of Kerry and Connemara. In the former, 110·40 in. fell at Gearahameen, and in the latter, **114·82 in.** at Delphi Lodge.

Districts of Least Rainfall.

In England less than 25 inches was confined to very small areas in the Fen District and on the coast of Essex. The smallest fall for any appreciable area was **about 22 inches** between Chatteris and Ely. In Wales less than 30 inches fell over most of Flintshire and on the extreme coast fringe of Carnarvonshire, with a minimum of rather **more than 25 inches** in the neighbourhood of the estuary of the Dee. The lowest rainfall in Scotland undoubtedly occurred round the shores of the Moray Firth, where rather **less than 30 inches** fell. It will be observed by the map facing p. [115] that the Firth of Forth area and the coasts of Haddington and Berwick, usually nearly the least rainy parts of Scotland, had, in 1916, a rainfall very largely in excess of the average. In Ireland only an interrupted and narrow strip on the east coast and a small part of the middle Shannon basin had less than 35 inches, and it is possible that small parts of the coast of Down had **less than 30 inches**.

Summary.

The rainiest part of the British Isles represented in the tables for 1916 was undoubtedly in the English Lake District, with a maximum of practically 200 inches, both Snowdonia and the West Highlands failing to give such high values. The driest areas, and the only districts with less than 25 inches also lay in England, whilst the minima on the east coasts of both Scotland and Ireland were unusually moderate.

BRITISH RAINFALL, 1916.

PART III.

GENERAL TABLE
OF
TOTAL RAINFALL IN 1916
AT
5192 STATIONS
IN
GREAT BRITAIN AND IRELAND,
WITH THE NAMES OF
THE OBSERVERS
OR OTHER AUTHORITIES FOR THE OBSERVATIONS.

COMPILED UNDER THE DIRECTION OF

HUGH ROBERT MILL,

Director,

BY

CARLE SALTER,

Assistant Director,

of the British Rainfall Organization.

62, CAMDEN SQUARE, LONDON, N.W.

EXPLANATORY NOTE.

The counties are divided up into numbered areas, corresponding to the river-basins. A full description of these river-divisions for England and Wales was given in a special article in Part I. of *British Rainfall, 1910*, (pp. 37—66), and a similar article on the river-divisions of Scotland and Ireland appeared in Part I. of *British Rainfall, 1911*, (pp. 49—72), with detailed maps showing all the river-divisions in each Division.

The Divisions in the General Table are the same as those adopted by the Registrars General of England and Scotland. The stations in each river-division are arranged nearly in the order of their latitude from South to North.

For convenience, the first name is that of a place which can be easily found on any large scale map; the second name is added to fix the site of observation more closely. In a very few instances, when in [] instead of (), it is that of the nearest town in an adjoining county; e.g., "Haslemere (Courts Hill)" means Courts Hill, near Haslemere, both in one county; but "Geldeston [Beccles]" means Geldeston near Beccles, which is in another county.

In the column headed "diameter," figures in old style type indicate the length of the sides of rectangular gauges.

The letter D signifies that daily observations have been received and are complete for the year. M indicates that the gauge is read only once a month. (R) denotes that the gauge used is a self-registering or a recording instrument, the correct reading of which depends upon the mechanism being in working order.

When the words *per* M.O. follow the name of the Observer the record is printed on the authority of the Meteorological Office. M.O.S. indicates Meteorological Office, Edinburgh, and S.M.S. Scottish Meteorological Society.

The total rainfall is printed in ordinary type under the heading of the unit in which the readings were made, *i.e.*, in inches or millimetres. The total as converted from inches to millimetres, or from millimetres to inches, is printed in old style type. If the record was taken during part of the year in inches and part in millimetres, the figures in both columns are printed in old style type.

A few entries of total rain will be found in italics—indicating that the values have been corrected, *e.g.*, when snow has been lost, when the amount for a short period has been computed from other records, or when the gauge has been moved a short distance during the year. The rule has been observed that a record is not printed if the gauge has been moved more than a mile, or if there is a greater difference than 50 feet of altitude between the two positions.

A dagger (†) denotes that the rain gauge has been visited and examined, or the site for it personally selected, by the Editor or one of his assistants. A note of interrogation (?) implies doubt, not necessarily error; it is not intended to cast any suspicion on the accuracy of the Observer. The absence of information is indicated by ...
